STATE LIBRARY.

Extract from the Political Code.

SECTION 2296. Books may be taken from the Library by the MEMBERS OF THE LEGISLATURE, DURING THE SESSIONS THEREOF, and by other State officers at any time.

SEC. 2298. The Controller, if notified by the Librarian that any officer has failed to return books taken by him within the time prescribed by the Rules, and after demand made, must not draw his warrant for the salary of such officer until the return is made, or three times the value of the books, or of any injuries thereto, has been paid to the Librarian.

SEC. 2299. Every person who injures or fails to return any book taken is liable to the Librarian in three times the value thereof.

No person shall take or detain from the General Library more than two volumes at any one time, or for a longer period than two weeks. BOOKS OF REFERENCE SHALL NOT BE TAKEN FROM THE LIBRARY AT ANY TIME.—[Extract from the Rules.]

The Foregoing Regulations will be strictly enforced.

VOLUME XLI
Number 1.

First Locomotives in America.

It is about 50 years since the locomotive engine was introduced in the U. S. It came to us from England. Among the many British experimenters with engines for the railway, it is generally conceded that George Stephenson was the first who successfully applied the locomotive to practical use. The railway had been in use in England for years, and many ingenious devices had been tried to supersede the use of horses, the most promising of which, for a time, was the stationary engine. At last the superior judgment and mechanical skill of Stephenson enabled him to avoid or obviate the defects in the machines of Brunton, Trevithick and Blackett, and he succeeded in constructing a locomotive engine, the first successful experiment with which was made on the Hatton colliery railway in 1822. Later on, in the year 1829, in contending for the prize of £500, which had been offered to the builder of the locomotive engine that should most fully meet certain specified requirements, Stephenson's celebrated locomotive Rocket, carried off the prize against three competitors. This successful engine weighed 4½ tons, and made the distance of 12 miles in 53 minutes. An English engine, built about the time of the Rocket's contest, was the first locomotive that turned a wheel on a railroad in the U. S. This is, perhaps, the sum of our indebtedness to England for the locomotive engine; and the obligation has long since been repaid to the fullness of usury, by a series of splendid improvements which have brought the locomotive engine to a state of refined perfection.

The question of priority in the use of the locomotive on railroads in this country is one of perennial interest. The literature on the vexed subject comprises volumes. For the seven cities of Greece, which claimed the honor of the birthplace of Homer, we have had almost as many States claiming the honorable distinction of first introducing the locomotive engines for service on the railroad. The idea of applying steam as the motive power on railroads had occurred to many of our engineers, stimulated as they were doubtless by the successful practice of England; and the introduction of the locomotive by Pennsylvania and South Carolina was almost synchronous; yet the former is fairly entitled to the distinction of priority.

Fortunately there is now living in San Francisco one of the veteran railroad men of the country, who is absolutely familiar with the interesting incidents of the early history of the railroad and the locomotive engine in this country, "all of which he saw and part of which he was." The name of this veteran is David Matthews, now nearly three-score-and-ten. He is a worthy representative of the American mechanic, at once intelligent, alert and trustworthy. In the course of an entertaining conversation with Mr. Matthews recently, we learned that he was born in Scotland and arrived in this country at the tender age of seven, and that a few years later he was sent to the West Point foundry shops in New York City to learn the trade of machinist. It was at these West Point machine shops that the very first American locomotives were built, and where the first English locomotive brought to the country was received and set up and exhibited. And it was also at those famous machine shops that Mr. Matthews met the distinguished engineer, John B. Jervis, whose name and fame are identified with some of the most remarkable engineering projects of the country, and who was the inventor of the plan of putting a truck under the forward part of the locomotive to direct and control the machine in running upon curves—a practice that is now universal and indispensable in the United States where the railroads follow the face of the country. Mr. Matthews has in his possession a copy of the "History of the First Locomotives in America," by W. H. Brown, published in 1874—a book which is chiefly valuable for the information respecting our early railroads which the compiler gleaned from Mr. Matthews and such early and distinguished engineers as Jervis, Allen and Latrobe. The testimony adduced from these intelligent and trustworthy sources is absolutely conclusive; and it would seem that it ought to

end the controversy about the claim to priority in the first practical use of the locomotive engine in this country. This well attested evidence shows:

1. The first locomotive engine placed and tried on any railroad in America was called the "Stourbridge Lion," and was imported from England for the Delaware and Hudson canal and railroad company. This engine arrived in New York May 17, 1829, and was set up in the yard of the West Point foundry machine shops and publicly exhibited for days to thousands of the first citizens of the country. It was brought from England by Horatio Allen, who made the first experimental trial of it at Honesdale, on the banks of Lackawanna creek, Pa., August 8, 1829, when he "opened the throttle valve of the locomotive engine that turned the first driving wheel on an American railroad." This highly interesting statement was made by Mr. Allen in a speech delivered at Dunkirk on the occasion of the celebration of the completion of the New York and Erie railroad.

trial was made with this locomotive, without any cars attached, at which trial Mr. W. B. Ewer, one of the proprietors of this paper, was present. It was on this occasion that the first American built locomotive turned its wheels for the first time on a railroad track. At the trial on November 2d the wooden wheels of the machine, which were constructed after the English practice, sprung and got off the track; but they were replaced by cast iron wheels, and on December 14th and 15th the engine was again tried and ran at the rate of 16 to 21 miles an hour with five cars carrying about 50 passengers, and without the cars it attained a speed of 30 to 35 miles an hour. In the Charleston Courier, March 12, 1831, there is an account of a later trial of the speed of the "Best Friend," on which occasion, the writer remarks, "safety was assured by the introduction of a barrier car, on which cotton was piled up as a rampart between the locomotive and the passenger cars." The second locomotive for service built in this country was called the "West Point," and was

to enable it to turn sharp corners easily and safely. The machine so constructed was called the "bogie" engine. The first of these engines ever built was for the Mohawk and Hudson road, and was called the "Experiment." It was put on the road and ran by Matthews, who says it was as "fleet as a greyhound." The "Experiment" had been built to burn anthracite coal solely; after a while it was rebuilt and adapted to the use of any kind of coal, and its name was changed to the "Brother Jonathan." Shortly after these changes had been made the English locomotive "Robert Fulton," belonging to the same company was also rebuilt and furnished with the truck, and named the "John Bull." The "Brother Jonathan" was a remarkable machine for those pioneer days. Mr. Matthews says of it: "With this engine I have crossed the Mohawk and Hudson railroad from plans to plans, 14 miles, in 13 minutes, stopping once for water. I have tried her speed upon a level, straight line, and have run a mile in 45 seconds by the watch. She was the fastest and steadiest engine I have ever run or seen, and I worked her with the greatest ease." This is certainly wonderful speed, and may be, as Matthews earnestly maintains it is, the fastest time at least on the American railroad record.

In comparison to this splendid and efficient engine of to-day, our first locomotives, built after the English model mainly, were clumsy and crude machines. Since then our improvements have been manifold and extraordinary, and the American locomotive is now pronounced the most "perfect railroad tool in the world." Its exquisite symmetry and flexibility, and its extraordinary power must fill the mind of a veteran like Matthews—who has watched its growth from its infancy in this country—with feelings of generous admiration and pride. The English and the American railroads and locomotives are strikingly contrasted by a writer in Harper's Magazine for March, 1879. English roads are short, solid, straight and level, and laid with the best rails in this world; and their massive and powerful, and rigid-framed engines are thoroughly adapted to those perfect roads. On the contrary, the American road is generally of great length, and being necessarily cheap it "goes as you please." Over these eccentric roads the American locomotive adjusts itself to every change of level both across and along the line; it takes curves that would be impossible for the rigid English engine; and, finally, it runs over a crazy track, up hill and down, in perfect safety. It has been well said that all that the English engine can do on a perfect road the American engine will do; and much more than this, it will do work on any road, however rough, hilly, curved and cheap. The names of the first American locomotive seems to have been inspired, for it has in the largest sense proved our "Best Friend."

THE "BEST FRIEND"—THE FIRST AMERICAN BUILT LOCOMOTIVE.

2. The first locomotive built in America for a purely experimental purpose was the "Tom Thumb," which was constructed by the now venerable Peter Cooper. This little machine was built for the purpose of testing the feasibility of a locomotive sustaining itself while running over curves, which was a mooted point among the engineers and scientists of that day. The engine weighed less than a ton, the cylinder was only three and a half inches in diameter, the boiler was about as "large as an ordinary kitchen boiler," and was vertical, with gun barrels for tubes. The first trial was made on the Baltimore and Ohio railroad, from the depot at Baltimore to Elliott's mills, August 28, 1830.

3. The first locomotive engine built in America for actual service on a railroad was called the "Best Friend," and was constructed for the Charleston and Augusta railroad company. This pioneer locomotive (which is the subject of our accurate and handsome illustration) was built at the West Point foundry machine shops in New York City, and the work of fitting it up fell to the lot of Mr. Matthews. Immediately after the engine was completed it was placed on the company's road, and the first experiment with a train was made November 2, 1830, N. W. Darrell acting as engineer.

Some few days previous to the above date, or about the 20th of October, in accordance with a notice given in the Charleston papers, a public

for the same road. It was also constructed at the West Point machine shops.

4. The first locomotive built in America for a northern road was called the "De Witt Clinton," and was the third American locomotive. It was for actual service on the Mohawk and Hudson railroad. This engine, like the others, was built at the West Point machine shops, and was also fitted up by Mr. Matthews; and when it was completed he took it to Albany, June 25, 1831, and made the first excursion with a train of cars over the road August 9, 1831. According to Mr. Matthews's statement, the "De Witt Clinton" weighed 3½ tons, and hauled a train of 3 to 5 cars at the speed of 30 miles an hour. It is especially noteworthy that both the cab and the tender of the "De Witt Clinton" were covered to protect the engineer from the weather—a "happy thought" of honest David Matthews, for which all American engineers at least ought to hold him in kind remembrance. About the middle of August the English locomotive, "Robert Fulton," built by the younger Stephenson, arrived and was placed on the Mohawk and Hudson road for service in the middle of the following September.

These locomotives had been used and fairly tested both on the southern and northern railroads, and the necessity for a radical change in their construction had become evident. Very soon John B. Jervis devised the plan of putting the truck under the forward part of the engine

LIFE-SAVING STATIONS.—The sum of \$20,000 appropriated in the Sundry Civil bill for establishing 11 additional life-saving stations previously authorized by Congress, became available July 1st. Of this 11 new stations, the Pacific coast will have two; one at Point Conception, and the other at Bolinas bay. They will be constructed and fitted in a similar manner to the stations now in use, and it is contemplated that they shall be in order for service before next winter. Some difficulty is anticipated in selecting a suitable site for the station at Point Conception, owing to the extra-hazardous character of the coast; but the Life-Saving Bureau will take unusual care in determining the site.

PUBLIC LAND SURVEYS.—On the last day of June the Commissioner of the General Land Office, with the approval of Secretary Schurz, made the following apportionment of the sum of \$300,000 appropriated by Congress for surveys of the public land during the fiscal year, which began July 1st: To Arizona, \$10,000; California, \$35,000; Colorado, \$30,000; Dakota, \$30,000; Florida, \$8,000; Idaho, \$12,000; Louisiana, \$12,000; Minnesota, \$16,000; Montana, \$15,000; Nebraska and Iowa, \$15,000; Nevada, \$12,000; New Mexico, \$12,000; Oregon, \$16,000; Utah, \$12,000; Washington, \$16,000; Wyoming, \$10,000; leaving \$39,000 to be used according to the exigencies of the service during the fiscal year.

CORRESPONDENCE.

Notes from New York.

[By W. E. PARTRIDGE.]

The Topics of To-Day—A Chapter of Accidents.

The topics of to-day are the horrible accidents which have just happened. They are of such a character as to make thinking men look with dread upon our harbor filled, as it is, with light, fast river steamers loaded at almost every trip to their full legal capacity. Their rate of speed is generally high, and though many of them are staunch and well-built boats, there are great numbers of them so small and light that they would ensnare like egg shells if struck by the heavier steamers among which they ply. Perhaps it is because they are supposed to be run by sailors that they escape. It is said that Providence watches over children, drunken men and sailors, or, as the latter puts it, "there is a good little angel that sits up aloft and looks out for poor Jack." Certainly his own watchful care would not prevent a thousand deaths by collision in this harbor every season.

Occasionally we have an accident which gives a hint of what we may expect if we do not make most radical reforms both in construction and management of the steamers and railway trains which run to our watering places.

Accidents to Come.

All New York feels itself in duty bound to go to Coney Island every hot Sunday. On every warm or hot day during the week as many go as can get the time and the necessary 50 cents. The rush is immense, and the demand on the railroads is for the lightest and most open cars that will hold the greatest possible number. How many "excursion" or open cars with cross-seats the Coney Island roads own it is hard to say. They make up very heavy trains of them and run at a high rate of speed. These cars are merely platforms with the lightest possible superstructure. There is nothing continuous above the floor except the roof. In case of an accident of any kind, whether collision or the ditching of a train, the passengers would be spilled out to take their chances with broken seats, trucks, wheels and miscellaneous wreckage. It is enough to make one's hair stand on end to think what would be likely to happen.

Your Felton railroad accident, as far as I can get at the details, was of this character. The cars are reported to have been open, and a small accident at 20 miles per hour sent the passengers on flying among the wrecks of the cars. With a good, strong car body to protect them, the whole affair might have been only recorded as the ditching of a train with a few bad hurts, but nobody killed outright. Be that as it may, we are preparing to have a first-class smash between New York and Coney Island when we get a chance. When it comes it will show that New York can beat the world in a great many things. The

Precautions

Taken in the management, however, to run trains safely greatly diminish the risks by reducing the liability to accidents. In this respect the Supts. of most of the roads deserve a great deal of praise. They are working evidently to the best of their ability. Col. Ricker, I think, understands the danger and is trying to guard against it on his roads.

The Burning of the "Narragansett"

Was one of the most horrible things that has happened in New York waters for many a year. Both boats of the line, the *Narragansett* and the *Stonington*, are old. If this had not been the case, the *Stonington* would have almost cut her sister boat in two at the speed she was going. This opinion is founded on the condition of her bows, which are badly shattered for some distance on each side. Life-boats and life-rafts were out of order, or lashed fast, so that they could not be used. Plugs were out of the boats and cars missing, and, to crown the whole, the officers are reported to have played the coward to perfection. I believe they all saved their skins, some of them without getting wet, if the accounts can be trusted. The captain says he was the last to leave the vessel, and yet he took command of one of the first boats lowered and was carrying passengers off to the *Stonington* all the time. Evidently the stories have not been rehearsed sufficiently.

The Fire

Was rather extraordinary, and goes to show that the conveniences which are so freely used on the great palaces plying on the sound, may be source of great danger. Most of these steamers, as well as those on the Hudson river, are lighted by gas, which is stored in large gas-holders. In some steamers these are on the hurricane deck in the wake of the paddle-wheels, as in the case of the *Massachusetts*. It is supposed that the holders, which are immense rubber bags, were broken when the crash came, and the gas at once took fire from the furnaces. It is said that the fire started very suddenly and had great headway almost at the moment it was first seen. A broken gas tank is in every respect worse, as a means of setting a fire, than

oil. The latter flows about, but the gas carries fire in all directions, and cannot be washed by any common fire apparatus.

The Moral

Of this accident may seem evident to most engineers, but from some vague whisperings I heard to-day, but hardly dare to mention, I should almost be ready to suggest Judge Lynch to hold court at headquarters. The condition of the life boats and rafts of passenger steamers generally in the harbor are enough to startle the bravest men. They do well enough as long as they are sitting in their chocks, but how they could be got out by their own weather-worn tackle and lowered into the water is a question that I don't want to answer.

The "Plymouth Rock."

One of the big excursion steamers, and once, I think, owned by Jim Fisk, had a funny accident the other day. When returning full from down the bay she suddenly began to swing round, refusing to answer her helm. A big crashing in the paddle-box gave the captain a hint of what was the matter. He is rather a cool genius, and went at once to the hand which was playing for dancers on the upper deck and told the leader to "make things lively" and keep doing so. When he opened the paddle-box he found the wheel had just twisted itself all to pieces on the shaft without doing any further damage. The musicians prevented a panic, when the captain set the whistle going as a distress signal.

When the other paddle-wheel gives out there will not be much left of the original boat. This was a funny little accident and no harm was done, so the inspectors say nothing; but suppose it had happened, say two or three days later, on Sunday during the squall, with the steamer outside the bay, say at Brighton beach. The wind would have played the mischief with her, and it would have been almost impossible to have escaped without a loss of life. She is one of the most lofty and top-heavy of our excursion boats, and is very unsteady. The squall, which lasted only for a short time, made it very lively for the *Grand Republic*, which was caught out in it. There was for a time some danger of a panic. Fortunately there was no sea on and no harm was done.

The Collision at Sea.

I had hardly finished writing the foregoing when the news came of a collision which took place on Sunday afternoon (13th) about 300 miles to the eastward of New York, between two ocean steamers. One of the vessels was the *Anchoria*, of the Anchor line. She had left New York the day before for Europe. The other vessel was the *Queen*, of the National line, bound in the opposite direction. The telegraph long before this has given you an outline of the accident. There was a thick fog at the time, and though they heard whistles the vessels were pretty close together before anything could be seen. Meeting almost end on, the *Queen* was turned so as to pass to the right, while the *Anchoria* attempted to pass to the left. The latter vessel, having a greater speed swung faster, and was struck in the side by the *Queen*, leaving a great hole, and filling two of her watertight compartments. That nobody was hurt was wonderful, and that one vessel with her side ripped open, and the other with her bow stove in should be able to steam 300 miles to a port seems almost incredible. It is hard to believe a plain statement of this wonderful accident, and the almost miraculous escape of the passengers. From an engineering point of view the lessons taught are very important. The public are greatly rejoicing over the

Value of Compartments.

As shown by the escape of both vessels. It is questionable upon examining the *Anchoria* whether she would have lived an hour had there been a heavy sea running at the time or afterwards. How deeply she sank in the water from the loss of this buoyancy may be judged by the fact that she came up to the harbor drawing no less than 39 ft. of water. A moderate sea would have probably broken her in two or swamped her.

It is said by several passengers, that the *Anchoria* was going

Full Speed in the Fog.

But the captain states that it was only 12 miles (11 knots) per hour. The other vessel was slowed down to 6. If she had been going faster she would have probably been injured less, but would have cut the *Anchoria* in two.

How Did It Happen?

This is a question that is being asked, but both captains refuse to say a word in regard to what signals they made or what orders were given to their quartermasters or engineers. The companies both issue orders that their captains must not talk about accidents. So, as there is likely to be a law suit, they keep their mouths shut. They have said a few things, however, and the passengers have told all that they know, and in this way considerable light has been thrown upon the subject.

Steam-Steering Gear.

The captain of the *Anchoria*, it seems, considered that, as he had a steam-steering gear to depend upon, he was justified in keeping up a good rate of speed, and if he had known how to use it, this would have no doubt been right. It is a well-known fact that most steamers will turn off at right-angles to their course, if going ahead at full speed, in a less distance than is needed to bring them to a full stop. In other words, if land is discovered dead ahead, and the ship is close in shore, the safest course is to put

the helm hard over, and turn a corner, as a landsman would say. With steam-steering gear this is so quickly done that no time is lost, only a few seconds being needed, as against a minute or more when manual labor is needed for the work.

Steering Screw Steamers.

Screw steamers have been in common use for 30 or 40 years, and during the last 10 years they are the only steam vessels used to any extent for ocean voyages, and yet sailors do not seem to have learned how to steer them. Even when going straight ahead, screw vessels do not behave in the same way as a paddle boat, for the screw is constantly tending to throw the head of the vessel in one direction, and the rudder has to be used to counteract this. When the screw is backing, this action is commonly reversed, yet this fact is not generally recognized by captains. When the screw is going astern, and the vessel still has headway, the whole action of the rudder in one position is reversed, and in another either neutralized or reversed. In examining the accounts of this accident we find that it is clear that the engines of one of the vessels, the *Anchoria*, were backing.

The Rules of the Road.

Landsmen do not generally get a very clear idea of the "rules of the road," as sailors term the directions given by law for passing at sea. Usually in writing about the subject, sea phrases are employed and the matter becomes a puzzle. In the present instance the vessels were meeting head on. Under these circumstances the rule of the road is, in "plain United States," to "keep to the right as the law directs." Unfortunately, the English law, as well as the American, not only tells you what you shall do, but what you shall do in order to do it. It says that the helm shall be put to the left in order that you may pass to the right. The helm is always supposed at sea to be arranged so as to move in an opposite direction from the rudder. Now, what shall he do if, when the helm is as far over to the left as it will go, the vessel's head swings in the opposite direction from what it should?

These two vessels were meeting, as far as I can learn, so as to make a fair and square collision end on. The *Queen* kept her engines going, put her helm over to the left and began to swing to the right. The captain of the *Anchoria* seems to have

Lost His Head.

And was frightened afterwards, for he probably put his helm over to the left and then, without thinking of the result, stopped and reversed his engines. The vessel undoubtedly, from the moment that the screw made the first turn, began to swing rapidly to the left instead of the right, as he expected her to do. When he comes to argue the case in court, if he can prove that the helm was hard over to the left, and that his engines were reversed—"going astern, full speed"—he will probably gain his case in spite of the fact that reversing the screw had in fact reversed the rudder.

The Reason

For this change in the action is to be found, in a measure, in the fact that the screw, when going backwards, creates a forward or following current of water, which strikes the rudder on the back instead of the forward side. The "twist" of the screw is also reversed and that has its influence as well. Here is a fact that can be proven at any time, and has been shown in a great many cases, that is utterly ignored by law and by steamship captains in general. In this harbor not half the tug-boat captains seem to be aware of it. I have seen one more than once trying to get a boat out of a snarl who was entirely ignorant of the fact that the twist of his screw would have got him out of his trouble at once. There are captains on the other hand that know their boats to perfection and can turn them almost on their centers.

I have just learned a fact in regard to the

Steering of the "Narragansett."

Which throws some light on the cause of the accident. Both of the boats of this line, when heavily loaded as they were on the night of the accident, mind their helms very slowly, but when they do swing come round with a rush. The position of the *Narragansett* according to all accounts shows that she had begun to swing heavily. The *Stonington* on the other hand had hardly changed her course. The captains say that an echo in the fog confused the signals, changing by doubling the sound the signal for keeping to the right into one meaning to pass to the left. This afternoon I took a look at the

Bows of the "Queen."

While they are badly stove in at and below the water line, the bowsprit and rigging forward are not injured nearly as much as would have been supposed. Had she been far enough in advance of her position so that the two vessels could have struck bow on, or had she been struck in the side by the vessel going at a higher rate of speed, she might have gone to the bottom head first without saying by your leave.

An Absurd Law.

The general law of the world in regard to steamers, is that they must get out of the way of sailing vessels; if they do not and there is a collision, then the steamer has to pay the bill. Practically this is an absurdity. When any little 40-ft. open boat crosses the bows of the *Germanic* or *Arctica*, or any 5,000-ton steamer that cannot stop in half a dozen times their own length, the law says they must get out of the sailing vessel's way. It is not very differ-

ent from requiring the bigger mule teams on the coast to turn out or stop whenever a man with a hand-cart or wheel-barrow wanted the road. One of these days I hope the law makers will wake up to the fact that a steamer has some rights that a sailing vessel is bound to respect. When they do this they may think it worth while to call a congress of nations, and establish a common sense "rule of the road" for ships at sea.

I had intended to give you some new items about our elevated railroads, but matters afloat were of too much interest, so I send you a naval letter instead.

LAND PATENTS ISSUED.—The Commissioner of the General Land Office has forwarded to the Surveyor-General of California, a patent in favor of Anasto Carillo, his heirs and assigns, for land in the Government's half-mile-square reservation for light-house purposes, amounting to 160 acres within the exterior boundaries of the official survey of the rancho Penila de la Concepcion, Santa Barbara county. A Government light-house was erected there in 1852, and in the patent issued to Carillo in 1863, for the rancho, it was excepted and excluded therefrom. Last April Secretary Schurz held that that action was unauthorized by the law, and by his direction a patent is to be issued for the entire survey outside the reservation. The Commissioner has also transmitted for delivery a patent for two tracts of land, constituting that part of the rancho Agua Caliente confirmed to Mariano G. Vallejo. As patented, the survey contains an area of 1864 acres, and is situated in Sonoma county.

CARP CULTURE.—The *Mercury* is informed that Capt. Fieldsted, who resides about 4 miles east of San Jose, in the foothills, is experimenting in carp culture, and with excellent success. He has a pond 40 by 80 ft. in extent, and 8 ft. deep, fed by a living spring. Last July he procured, at a cost of about \$50, 10 carp, then 4 months old, and weighing about 2 lbs. each. These fish have now grown to from 6 to 8 lbs. in weight, and his pond is thoroughly stocked with young fish. He intends to construct another pond about an acre in extent, and give the fish a chance to spread themselves. The beauty of the carp, for marketable purposes, is the rapidity with which it matures—a few months only being required to bring it into use, while the trout is of but little account before the second year. In all our bill ranges, where living springs and streams abound, fish culture for food purposes could no doubt be made profitable.

SKELETONS FOUND IN THE SHAFT OF A MINE.

At Red Gulch gravel diggings, below the Columbia Crystal Palace cave, some Italians mining there, recently, came upon three skeletons, one of which had a pair of boots on in a good state of preservation. The appearance of the remains indicate that the persons were miners, and had been murdered (probably for their money) and thrown into a shaft or old mining hole; one body was lying across the breast of another. There were many Mexicans, once of a desperate character, hanging around Pine Log, and the North and South forks of the Stanislaus river during flush times of mining, in the early days of California. Near the Crystal Palace cave is a fresh water spring, the only one for miles around. The five acres surrounding it were for many years an old Indian ranch, where hundreds of the natives gathered annually for their harvest dance and summer festivals.

RICH DISCOVERIES ON WHITE RIVER.—The

Carbon County Journal (Wyoming Territory) of a recent date, says that Mr. A. McCargar, a special agent of the Interior Department, and well known throughout Colorado, Wyoming and the West, reports that James McGovern, an old miner and prospector, who has been prospecting up on White river, discovered, a short time ago, about 30 miles above the military cantonment, some very rich silver ledges, assays from which, made at Salt Lake City, gave a return of 700 ounces silver per ton of 2,000 lbs. A number of persons have left White river for the new El Dorado, and Mr. McGovern and party have ordered a large lot of mining tools, including a blacksmithing outfit, and will at once commence work on their locations. The ore is said to be a free milling silver ore.

RAILROAD BUILDING IN ARIZONA.—There are

now, says the *Los Angeles Express*, June 18th, six trains running between here and Arizona, two new ones having been put on yesterday. This makes a departure every day of three trains from each end of the road. The company are pushing on the work of extending the road with increased energy, and say that as soon as they pass the range of mountains the other side of the San Pedro, they will reach a country where they will be able to lay three miles of track every day. They are impelled to this great energy in their work by the rapid movement westward of the Atchison and Topeka road. That road is now so far advanced that Arizona merchants can lay down goods cheaper by it from the East than they can by way of San Francisco. It looks as if the days of competition among the great corporations were approaching.

A Norwegian manufacturer is filling an order from Australia for cast-iron axes, which will be traded with the natives in the northern part of the island for ivory.

MECHANICAL PROGRESS.

A Wonderful Advance in Fuel Arts—
Strong's Water-Gas System.

Some two years since, the representatives of the Strong water-gas process publicly announced that it was possible to convert the best anthracite coal to a gas which should possess a greater heating value than the fuel from which it was derived, for practical purposes. The objection was at once raised that there was an absurd attempt to extract from a given weight of carbon more calories than it contains. The charge was based upon the undeniable truth that the burning of C to CO implies the expenditure of a proportion of its heat, and hence the new form must represent less caloric energy than the old.

Prompt answer was made, admitting this last fact, but explaining that the objection was theoretic and not practical; that the comparison must not lie between the potential energy of a fuel and that of its gaseous product (except for certain limited purposes), but between their several actual energies. It was shown that the theoretic heating powers of fuels are determined by delicate laboratory methods, which, however precise and valuable, are utterly unobtainable by ordinary practice; that the steel makers of Sheffield utilize only 3% of the value so ascertained, consumers in the domestic industries not over 10%, while the most economical use of fuel ever attained, namely, in the largest and most perfect blast furnaces, does not exceed 36%. The better result claimed for some boilers was excluded from the comparison, on the apparently just ground that, as the generation of steam is specifically for the driving of engines, the utilization of heat should be judged by the power developed rather than the weight of water evaporated, and that, so judged, the loss is as great as in other fuel applications.

Evidence was then offered that in the combustion of the Strong gas it is possible to utilize within 10% to 12% of its full theoretic value, and it remained only to make a comparison of results, which was done substantially in the following manner:

One pound of anthracite possesses a potential energy of 13,300 units of heat, of which the actual energy, namely, that realized in practical operation is, as we have already seen, from 3% to 36% thereof, or 405 to 4,960 units of heat, according to the manner of its use. The gaseous products of one pound of anthracite, by the Strong system at that time, was 8,092 units of heat, and an actual energy of from 88% to 90% thereof, or 7,121 to 7,290 units.

Assuming for simplicity what is, perhaps, not an unfair assumption, that the labor-cost of conversion is compensated by collateral advantages in the reduced labor of using gas-fuels, the consumer was left to decide the simple question, from which form of fuel he would realize the greater number of heat units.

This answer on the parts of the advocates of the new system seemed intelligent and correct; at all events, it has never been controverted. Admitting it to be so, we must acknowledge also that the new method of converting carbon in unperheated steam, instead of atmospheric air, represents an important advance in the art of combustion.

More recently, additional facts of great interest have been developed by further experience with the Strong furnace more perfectly constructed. The opinion that a great variety of fuels could be utilized by it has been justified by the results, and the gratifying fact established that all yield nearly identical gases, the variation being not in quality but in volume, which is consistently in proportion to the amount of carbon contained in the fuel. The special excellency of this system in rendering available certain cheap and abundant forms of fuel, heretofore deemed inferior and so neglected, such as small coals, culm and peat-dust, and which were employed in the proportion of three pounds to one pound of the better grade, is now ascertained to have a more important significance than the utilization of cheap material, important as that is.—Geo. S. Dwight, in *Engineering and Mining Journal*.

MARINE ENGINES.—A writer in the *London Engineer*, on the subject of changes and improvements in the construction of marine engines, makes the bold assertion that some of the new colossal steamships recently built for the trade between New York and England hold out the probability that before many years steam navigation on the Atlantic will develop a speed but little if any inferior to that of the average express trains on first-class main lines of railway. It seems to be useless to attempt to dispute the possibility of an achievement of this sort in the age we live in, and without undertaking to discuss the point, our purpose at this time is to ask the very particular attention of iron shipbuilders in the valley of the Delaware to the extreme importance of keeping watch over the changes in the construction of English marine engines, and of the practical working thereof in the new steamships which we have referred to.—*North American*.

To ascertain the size of a driver multiply the diameter of the driven by the number of revolutions you wish it to make, and divide the product by the revolutions of the driver; the quotient will be the size of the driver.

Make Your Own Tools.

This ambition to individualize tools and to adapt them to their users is a characteristic of skillful workmen, and makes a broad line of distinction between the mechanic and the mere laborer. A kit of tools made by the mechanic himself is a recommendation of the mechanic. Few intelligent foremen sneer at this professional pride, or ridicule its visible products. And the possession of a kit of his own tools, made by himself, is not only evidence of the honorable pride of the workman, but is frequently a guaranty of his ability. A workman who can make a good kit of tools, who can shape a cold-chisel, construct a gauge, hang a hammer, or fashion an elegant and handy scratch-awl, and do other good jobs, evidences a pride in his own handiwork that will not be satisfied with half-don't jobs.

The desire of the mechanic to have his own tools made, or at least adapted, by himself, is perfectly natural. With the knowledge of the fact that individuals differ, comes the evidence that what suits the mass is not adapted to the one; that what is for all is not for this particular one. How many machinists are at home in handling a strange hammer? How often the workman drops a hammer he has picked up in haste, and delays an instant until he can reach for, or go for his own! This is not foolish fastidiousness; for those who most stick to their own tools are old, experienced workmen, who have outgrown the false pride which would make them insist on their way as the only right way. The fact is that the workman is the best judge of the adaptability of a tool for himself, and if he does not make and fashion his own, he at least chooses and modifies those produced by others.

This necessity, or the advantage of adaptability, received an illustration recently, when a smith, an expert forger of iron and steel, with 20 years' experience, showed the writer a hammer with a split handle, saying, "That is the best hammer in the shop to finish off a forging handsomely." The fact was that he had not dared to shave down the hickory small enough in the neck of the handle to give it the "feeling" spring to his hand, for fear of breaking it in use, when a foul blow in the hand of an apprentice split the handle, and made it the handiest one in the shop.—*Exchange*.

A POWERFUL TESTING MACHINE.—E. and T. Fairbanks & Co. have completed two or three large testing machines lately ordered by the Government to be used in testing the strength of iron and steel. These machines are very compactly built, occupying but about five ft. square on the floor, and about ten ft. high—all of iron and steel, and weighing four tons each. The metal to be tested is clamped securely between two heavy iron collars, which are drawn apart by two heavy screws turned gradually by hand with a combination of gear wheels. The testers are really weighing-machines also, having levers, beams, poise, etc., and as fast as the power is applied to the metal to be tested, the poise on the scale beam is moved automatically, indicating the number of pounds of strain applied. At a trial a bar of steel an inch and an eighth wide and five-sixteenths thick stood a strain of over 41,000 lbs. before it was pulled apart, and before it broke it was reduced in width an eighth of an inch, and in thickness nearly a sixteenth. So heavy and powerful are these machines that there was no perceptible recoil when the steel parted. The one tested as above is going to Cincinnati; and just to test its strength, a heavy bar of steel was placed in its jaws, and 100,000 lbs. strain put upon it without any visible effect.—*St. Johnsbury (Vt.) Caledonia*.

AVOIDANCE OF VIBRATION BY MACHINERY. Mr. W. H. Delano, in a paper read before the British Institution of Civil Engineers, suggests the use of asphalt for the foundation of machinery, notably for those running at high speeds, the asphalt having the valuable quality of absorbing vibration. This was instanced in the case of a Carr disintegrator, which, being mounted in a pit lined with bituminous concrete, was worked at 500 revolutions per minute without sensible tremor, whereas with the former wooden mountings on an ordinary concrete base, the vibration was excessive and extended over a radius of 25 yards. In the Paris exhibition of 1878 there was shown a block of bituminous concrete, weighing 46 tons, forming the foundation of a Carr disintegrator used as a flour mill, and making 1,400 revolutions a minute, a speed which would have been impracticable on an ordinary foundation. Extensive applications of the material for this purpose are made in France, especially in connection with steam engines and steam hammers.

AN IMPROVED MACHINE FOR WORKING METAL, WOOD AND STONE has recently been patented by Mr. R. R. Atchinson of New York, the main novelty of which is claimed to be the movement of the bits, which have a continuous rotary motion, as well as an alternating percussive stroke. This arrangement facilitates the work, while the tool is not subject to as rapid dulling as is usual with similar machinery. The new tool is said to cut granite at the rate of 45 square ft. per hour, the depth of the cut being 1-16 of an inch, the tool striking 6,000 blows per minute and outlasting one hour's work. The mechanism is similar for working wood or metals.

SCIENTIFIC PROGRESS.

"Evolution Admitted, What Then?"

It is gratifying to note an obvious subsidence of alarm on the part of eminent divines in regard to the acceptance of evolution doctrines, accompanied by the bolder enunciation of rational views respecting religion. Dr. E. O. Haven, Chancellor of the University of Syracuse, and now a Methodist bishop, sends a communication to a leading religious journal under the above title, which is full of significant foreshadowings that are worthy of notice.

Dr. Haven utters a very important truth when he says: "Men are prone to associate their religion with its drapery. This becomes obsolete and must be changed, and the looker-on fancies that the very body and soul are gone." This is the view of science. Religion, like other things, is progressive, and proceeds from stage to stage, successively molting its integuments with increasing expansion and a higher life, or, by the figure of Dr. Haven, shedding its worn-out clothing as occasion requires. It is a great point gained in this matter to discriminate between the living body and its accidental and temporary wrappings—between perennial truth and its obsolete accompaniments. The credal habiliments are not the vital thing they invest, and to cling to them as if they were is superstition. Dr. Haven's point of view enables us to appreciate the triviality of denominational creeds, its styles; and illustrates the futility of venerating theological rags and tatters instead of the essential religious ideas which require ever to be clothed anew as men grow in grace. And what a pitiful spectacle, moreover, it is to see people so confused and perverted in their notions as to actually worship the heaps of old clothes that have been long ago worn out and cast off.

We are glad to observe that Bishop Haven does not recoil from the conception of creation as a continuous, ever-unfolding work. He wisely accepts the view of God, compelled by evolution, as that of an eternally-creating Spirit. He says, "Is there any reason whatever to believe that God at any past period, large or small, had any more or less to do than now with this earth and all that it contains?" And again: "Had we all been educated in a theory of gradualism and constancy and improvement, and thoroughly saturated with it, and yet aroused into a profound belief in God, as is certainly conceivable on that theory, and then, should the theory of a Deity sometimes awake and sometimes asleep be suggested, it would shock some feeble minds into atheism." But would not strong minds also be thus shocked, and justly so; and would not the atheism be real? When evolution has become an established and familiar idea in the religions world, and the Creative Power is conceived—as far as such conception is possible to finite faculties—as the mighty, ever-energizing spirit of which the boundless universe is but the manifestation, a reversion to present current notions of the method of creation will assuredly be regarded as a lapse into atheistic paganism, analogous to a present backward plunge into fetishism.—*Prof. E. L. Youmans*.

ASTRONOMICAL.—A writer in the *Providence Journal* says: If the planet Neptune was discovered or supposed to exist on account of certain perturbations in the movements of Uranus, and if the erratic movements of Mercury reveal the presence of planets within his orbit, why should not the near approach of Jupiter to the sun stir up a commotion in his fiery elements? The sun is still diversified with spots, and the planet is near enough to perihelion to make his influence felt. Astronomers have been wise prophets thus far as to the influence of the commencement of the sun-spot cycle. Tornadoes and cyclones of extreme severity have borne witness to abnormal conditions of the atmosphere, and a wave of intense heat, such as has not occurred for a quarter of a century at this season of the year, has confirmed the exactness of previous observations. We must still expect the usual storms, waves of heat and auroral displays that follow the maximum of sun-spots; we have yet to learn whether the coincident perihelia of the four great planets will increase and prolong the elemental warfare. This is one of the most interesting problems of the day, as well as one of the most practical and important. It will not meet with a hasty solution, for the period of observation extends to the year 1855.

HERR RUDOLF FALE, a well-known astronomer, has returned from his travels in South America, and believes he has made important discoveries as to the original language of the human race.

A GERMAN chemist is said to have discovered a substance which may be used as a substitute for phosphorus in the manufacture of matches. We are not informed what the substance is.

M. DUMAS has observed that aluminium will occlude as much as one and a half times its volume of hydrogen gas, and traces of carbonic acid.

The Fossil Man.

Prehistoric archaeology, the latest-born of the sciences, like her elder sister, geology, has lived through the successive stages of scornful denial, doubt, and unwilling assent, and has finally won for herself substantial recognition. The "antiquity of man" is now an established fact. Even its most strenuous opponents are forced to concede that there are proofs of his existence during a lapse of time far exceeding the limits of the previously approved chronology. For somewhat of the suspicion with which this result has been received, certain of its advocates may have themselves to blame. Where absolute chronological determinations were of necessity impossible, and where, even at the present stage of the investigation, only general approximation can be reached, it was at least injudicious to startle received opinion, and to arouse prejudices, by asserting for mankind an antiquity of hundreds of thousands of years. Moreover, the great name of Cuvier was held up as a barrier in the path of those who claimed to have discovered proofs of man's existence under geological conditions different from the present. Cuvier, however, never denied the possibility of finding "the fossil man"; he only questioned the sufficiency of the evidence of his existence which had been brought under his notice, and with great reason, in view of the numerous instances in which pretended fossil bones had turned out to be those of animals, or even merely natural formations.—*H. W. Haynes, in Popular Science Monthly*.

MICROSCOPIC TESTS.—Mr. B. G. West has succeeded in tracing on glass the curves called after Lissajou. He has traced these in lines of 55,000 to the inch, and finds that they are much better for testing the power of a microscope than straight lines. Aside from their great beauty, and the necessity of skillful illumination to see them well, the intersection of some lines and the gradual approximation of others, arising from the variation in the figures, where every degree of the sharpness of a curve is obtainable, from a line returning almost upon itself at an exceedingly acute angle, to curves so flat as to present in parts virtually the appearance of parallel straight lines—all this, combined with a knowledge up to a certain point of the nature of all lines cut in glass, makes these rulings more instructive perhaps than the markings on diatom valves, in regard to which there is as much question. A curious feature of some of these figures is that though all the lines would seem to be in the same plane, it sometimes happens that an alteration of focus is requisite to bring out the transverse lines. The same fact has been noticed in observing the transverse markings of the diatoms.

SOURCE OF MUSCULAR POWER.—The theory has been adopted by many physiologists of late years that the muscular system of a fully developed man, or other animal, in health, is merely a perfected mechanical apparatus which accomplishes work like a machine, not at the expense of its own substance—replacing it by the assimilation of food, but using the food directly, converting it into force without transforming it into muscle. Dr. Flint, however, in a recent work, examines this theory and gives the results of a series of observations by himself and others, having for their object to test its correctness. After the most careful tests practicable, his conclusions are in opposition to the theory of direct food conversion, and lead him to adhere to the older assumption of muscular waste and repair, the muscles being their own source of power.

SALICYLIC ACID IN DRINKING WATER.—Prof. Kolbe, the discoverer of the antiseptic properties of salicylic acid, recommended some time ago that drinking water, used by sailing vessels on long voyages, might be preserved from fouling by the addition of a small quantity of this agent. Experiment has shown, however, that this expectation is not realized where wooden casks (untarred) are used. The wood substance appears to completely destroy the acid, so that after a very short time not a trace of it can be detected. The same experience has been made with salicylized wines in casks.

THE SURVEY OF THE GULF STREAM.—The sundry civil appropriation bill, just passed by the House of Representatives, provides for a survey of the Gulf stream from its origin to its final whirl around the Sargasso sea. The plan embraces soundings, deep-sea temperatures and current observations. The high importance of the proposed survey is clear and when done it will add another valuable chapter to the nation's record of scientific explorations. The practical value of the proposed work, in its bearing on commerce and meteorology, is beyond estimation.

A NEW ELECTRICAL PRINCIPLE.—Prof. Lemstrom, of Helsingfors, has made the singular observation that a ring of insulating material, when rotated about its axis of symmetry with a high velocity, acts like a galvanic circuit, and produces a magnetic "field" in the space within it. This experiment is quite inexplicable, and *London Nature* is disposed to regard it as a fundamental fact in the physical theory of electricity.

We understand, says the *Reese River Reveille* of June 24th, that an important strike has recently been made in the Alameda mine, adjoining the Brooklyn, at Grantsville. We are not in possession of anything farther pertaining to the development.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals

ASSESSMENTS-STOCKS ON THE LISTS OF THE BOARDS.

will be repaid by a handsome reward. The mine is running with 1,400 inches of water, of which 1,050 inches are forced through a 7½-inch nozzle by 250 ft pressure.

EL DORADO.

YOUNG HARMON.—*Mountain Democrat*, June 26: This mine has been prospected by several different parties at different times, but none of them seem to have had the means of doing the work thoroughly. The present owners are sinking a main shaft and also a winze in the tunnel. Some very rich rock has been taken out. A wagon road is being constructed from Camblers' gulch, and the 10-stamp mill there is being completely renovated.

WEBER TUNNEL.—This tunnel has reached the shaft at Coon Hollow. Drifts will now be run in various directions to determine the character of the gravel.

PLACERVILLE G. O. Co.—The hurdy-gurdy wheel which drives the company's mill is about to be changed for one of another form; the inventor, Mr. Knight, claiming a great saving of water over the present one. About 30 tons of quartz per day is the average crushing at this mill—nearly 1,000 tons per month.

PLACER AND GRAVEL TREASURES.—Some new and very rich placer ground has been found near Brownsville which is creating quite a stir in that neighborhood. The ranch on which the discovery was made has been put into claims, and lively work is being done. Gil Knox and Charley Varozza have driven a tunnel 150 feet into the gravel on the hill, over the Sacramento road. They are now in gravel 3 feet thick, which prospects from 5 to 15 cents to every pan. **GEORGEOWA NOKS.**—There has been a strike of gold for some time, but it is not yet known whether it is a vein or a bring water on Spanish Flat and divide from rock creek.

OLD CHICKEN FLAT MINE.—The machinery for this mine is on the ground. This is another large, well-defined lode, 8 ft wide on the surface, and gradually widening as it goes down. There are about 300 tons of ore now on the dump, from which about \$30,000 have been taken by the miners process, and still the ore will pay from \$5 to \$14 per ton, by mill.

GOSHUTE MINE.—This mine is prospecting well. They are crushing rock, and the battery plates showed well after 14 tons had been put through.

KAPERANZA.—This mine will probably have a mill upon it in a short time. This is a lode of great strength. It is over 30 ft in width at a depth of 170 ft, and traceable through the country 1½ miles. There is no doubt of its richness.

ITEMS.—The Chaparral mine is erecting a 10-stamp battery, which will be ready to run in a short time. The Rising Sun is worked with a 4-stamp mill, of about 4-ton capacity, and it is said that this small mill one-half of the proceeds is profit. Parties connected with the C. P. R. came up lately looking into some of the mines in Greenwood district, in which they were interested. They have purchased the Lemann claim at Hogg's Diggings for \$10,000.

INYO.

HARSEN MINE.—*Independent*, June 19: The mine is situated about 1,200 ft above the valley, and consequently over 5,000 ft above sea level. It is a 4-ft ledge, carrying 3 ft of ore, and lies in a general strike in a general formation of slate and limestone. The ledge has been opened in 2 places; in 1 to the depth of about 20 ft, and several tons of ore have been extracted. From a small streak on the west wall of the ledge comes a heavy, black ore carrying lead, copper and silver. In the center is a gray quartz, bearing both gold and silver. The bulk of the ledge, however, is a heavy, red oxide of copper, and the seams of which are found filled with chunks of native copper.

BEVERIDGE DISTRICT.—Messrs. McEvoy & Taylor, of the Freeborn Canyon Works, Beveridge district, came in lately with 63 ounces of fine gold. This is the result of an experimental run on a new mine, the ore of which does not appear to have worked more than \$30 per ton, although only a partial clean-up was made.

BISHOP CREEK NOTE.—J. Stoutenborough, on his return from San Francisco, became quite elated at learning that there was a strike on his desert land claim. Experts say there is no telling where it will lead.

RESTING SPRINGS.—*Cor. Independent*, June 13: This camp has not been worth speaking about for the past 3 months, but lately it has been galvanized into new life by the arrival of C. E. Luckhardt, M. E., from San Francisco, and who has full authority from the company to do as he pleases. He is now in charge of the camp. The mill is running day shifts only, but to-morrow will begin to run day and night. Most of our people had got tired of waiting, and have struck out for newer and better camps.

MONO.

BODIE DISTRICT.—*Free Press*, June 22: During the week 1,044 tons of ore, from the 300, 400, 450 and 550 levels of the Standard Con., were extracted. The average pulp assay was \$31.33. The amount of crude bullion received was 4,510 ounces, and the amount shipped by the company, \$45,048.07. The new shaft has been sunk and timbered since last report 7 ft, making a total depth of 342 ft.

LAST CHANCE.—*Supt. Graham's* weekly report of the 19th inst. says: "Since my last letter I have uncovered a ledge 5 ft wide, with a regular hanging and footwall, and of good milling ore, which has been taken out. The amount of ore during the week, same period, 417 tons of ore, from the 200, 300 and 400 levels, were extracted, the average assay of the pulp being \$10.02. The south drift on the 300 level has been advanced 17 ft on the Ralston vein. The south drift on the 400 level has been advanced 24 ft on the Stonewall vein. The stopes continue about the same.

SUMMIT.—The south drift has been extended 12 ft; total ledge, 83 ft. The ledge is 12 ft wide. The east crosscut has been advanced 25 ft; total length, 90 ft. The face is in hard-blasting ground. The south drift, east Summit vein, has been run 12 ft; total length, 35 ft. The ledge is 3 ft wide. The upraise on this ledge is up 20 ft. The ledge is 4 ft wide.

ADDENDA.—The east crosscut is now advanced from the station 25 ft. The amount of quartz and ore coming in the face. The indications are that they are over the ledge. The east crosscut has been advanced 48 ft.

SOUTH NOONDAY.—*News*, June 22: The north drift on the 250 level has been advanced 12 ft during the week; total length, 36 ft. The whole face of the drift is in ore of a good quality. The ledge is fully 10 ft in width, and is steadily improving as progress is made.

QUEEN BEY.—The south drift on the 400 level has been advanced during the past week 25 ft, making a total length of 146 ft. The ledge has been constantly improving in strength and quality, and now shows a face of 5 ft of good milling ore.

SOUTH BULWER.—South drift on the 550 level has been advanced during the week 12 ft; total length, 33 ft. North drift, same level, advanced 14 ft; total length, 42 ft. Face from south drift has now attained a depth of 14 ft. In all the different workings the ledge is looking well and carrying a fine quality of ore.

MARYLAND CON.—The south drift, 250 level, of the Maryland Con. has been driven 125 ft. A vein 2 ft wide, in a soft porphyritic formation, was struck at the bottom of the old incline shaft. Passing into hard rock further south, this ledge again became an almost invisible seam, but quite recently this has widened—again in a soft formation—to fully 2 ft, and is still widening. Assays of ore taken from the face of this widening vein run up to \$60. The 3 ledges cut by the east crosscut, 500 level, are full of good milling ore.

MAMMOTH DISTRICT.—*Herald*, June 23: Good headway is being made in the shaft sinking on the Last Chance mine, the ground being very easy. The southern portion of Mineral hill is fast coming to the front with its many rich ledges of gold and silver.

NOTES.—B. N. Lowe, of Lake district, on Monday visited some of our mines, including the True Blue, Monte Cristo, and other mines on the top of Mineral hill, and was highly pleased with the general outlook.

THURSDAY DISTRICT.—The miners are informed that a party of miners arrived from Fresno last Saturday to commence their summer's work in this new district. There are many large ledges in the district, from which assays rich in gold and silver have been obtained from the croppings. The character of the ore is similar to that found on the rich

surface croppings on Mineral hill, in this district, and appears to be a continuation of the same. **BENTON DISTRICT.**—*Cor. Mammoth City Herald*, June 19: Work has been resumed at the Clover mines. The Wild Rose is looking fine. The tunnel connected last fall is now in the ledge some 18 ft, and no signs of the outer wall. They have run 2 drifts to find the 2d wall—1 south, the other north. I saw 3 assays made from the mine that went as follows: No. 1, from the north drift, \$31.21; No. 2, from the bottom ledge, 1 set No. 3, 3 ft, from the south drift, \$24.80. There is a small streak in the mine, which increases as they sink, that goes in the hundreds—from \$900 to \$900. The Oro Fino will be worked this fall and the coming summer.

NEVADA.

EMPIRE MINE.—*Grass Valley Union*, June 26: As soon as the mine is pumped out, the work of sinking the main incline for another level will be commenced. The Rich Hill lead will also be worked through the crosscut from the Empire. In the Empire mine, above the level of the drain tunnel, there is considerable ground that can be now worked, and the company will let out to tribute.

DRAWING MINE.—The Dobree drift mining company, of North Bloomfield, (and has been for some time past) in a very rich body of gravel, and the deposit has every indication of possessing greater permanency than the most sanguine friends of the property formerly hoped for. During the past 30 days the clean-ups have averaged fully \$500 per day. The company will at once make arrangements for commencing work on a short tunnel which it is expected will produce enough gravel from the start to pay the cost of running. When this is completed it is contemplated to run a long tunnel, working at both ends and pushing it through as rapidly as possible.

GOLD RUN M. Co.—The Supt. informs us that he has put a force of 15 men at work on this company's claim down at Gold Run. They commenced work this week, making preparations for their work on the short tunnel, in which they expect to arrive from San Francisco in less than 10 days. The mill will be used for crushing the hard cement gravel immediately on the bedrock, which is too hard to wash without first being crushed.

MERRIFIELD MINE.—The Merrifield ore carries a large amount of auriferous sulphurets, and for the efficient and economical working of the same it has been determined to erect extensive elimination works for their reduction. The works are to be constructed with all the modern improvements. The main building will be 90 by 68 ft, with store-room, vat-room, furnace, smelting-room, etc.

AMERICAN MINE.—*North San Juan Times*, June 26: This mine is looking well, and the ground they are now washing looks as though it would pay well. The company is working the mine as economically as possible. Since the construction of their water pipe, they have now covered the mine formerly, because of less friction. The mine was never in a better condition for working than now.

SOUTHERN CROSS AND POLAR STAR.—*Dutch Flat Forum*, June 26: They had a clean-up in the Southern Cross mine last week. We are not informed as to the amount of gold taken out, but it was quite large, judging from the fact that the company owning this mine has been hiring and sending out men to work on the mine, and some of them have more. The work, both in the Southern Cross and Polar Star mines, is being pushed along as rapidly as possible.

ITEMS.—We understand the Cedar Creek ditch company's ditches and mines will change hands in a few days. It is the intention of the new owners to put the ditch in thorough repair and commence operating the mines soon. **FOUSTAIN HEAD MINE.**—*Cor. Herald*, June 26: Lately the company owning this mine has been working on the north side of the ridge near Fraser's ranch. The incline on the south side, which had reached a depth of 80 ft, has been abandoned. The projectors expect to be compelled to sink some 400 ft before tapping the channel. The Cold Spring tunnel has indicated recently that the lead extends along the north side of the ridge.

MEADOW LAKE.—*Cor. Transcript*, June 23: A New York concern has secured a great many claims in this district, and is now working the Badger. They have reached the ledge by means of a tunnel, and have crosscut it for a distance of 34 ft; all good ore, and at present have no indications of reaching the footwall. The shaft they are now sinking is down 70 ft, in ore all the way, but no crosscuts have been run to determine the width of the ledge. The first 15 assays made from the croppings and working level yielded an average of \$200 per ton, some of it running as high as \$900. Machinery has been ordered from the East to work the ore, of which they have a vast amount on the dump, and it is expected to arrive daily.

U. S. GRANT MINE.—Across Red Mountain from the New York company's works, we reach the U. S. Grant mine. The mill of this company, which was crushed by a snowslide in April, is being repaired. The have an 8-ft ledge carrying splendid assays.

GARFIELD M. Co.—The Caselle mining company, owning an extension of the Grant location, are developing their property, and have great confidence in its future value. The ledge where they are working is about 30 ft wide and gives good assays.

PLACER.

BIG GUM CLAIM.—*Herald*, June 26: The Van Emom Bros. are approaching the close of a short but very successful season. Their mine has paid better this season than it has any season for 10 years. At this time when the mine owners and capitalists are reducing the wages of their employees, this sterling old firm pay the same prices they paid 20 years ago, and their mine will enable them to do so for 20 years more. During the winter season they pay \$3.50 per day, and \$3 during the summer months. By this means they secure good, reliable men. Some of their present hands have served them for 15 years.

PLUMAS.

BELL MINE.—*National*, June 26: The strike in the Bell mine so far proves permanent, and a good showing of very rich quartz has been developed by the work. The ledge is 6 ft through, and is made fairly clean with good milling ore. The ledge is steady, as yet from rock from the upper levels, and is paying well.

RICH QUARTZ.—Rumor says that Mr. J. A. Edman is developing a high quartz mine in Eagle gulch, and that the owners have cleaned up over \$2,000 with a hand mortar during the past winter. They are putting up a large water-arabstra, and will make money at a lively rate when they get to work.

PEDERAS DITCH AND WATER CO.—This company is making a splendid run this season, and has already shipped over \$30,000 as the result up to this time. Last week a dividend of \$5 per share was declared. The water is yet "booming," and the run is not more than half over. They have an inexhaustible supply of gravel, and their big pipes do splendid work.

SHASTA.

SODA SPRING NOTES.—*Reading Independent*, June 24: The miners have begun to clean up, and their prospects are flattering. By the way, we have had some excitement on Soda creek in regard to Chinamen. One man proposed to sell some mining ground to Chinamen, and the miners called upon the party wishing to sell to persuade him that his contemplated action was not agreeable to the public at large. The Chinamen have nearly exhausted all the bars on the Sacramento river; also Dog creek and Slate creek. In fact, where they have been allowed to work, they have made a clean sweep.

FLAT CREEK MINE.—The Murray mine, considered one of the best mines in the district, is down about 80 ft, with a well-defined ledge of excellent ore. Six men, under the direction of Mr. Shepler, are now engaged in running a tunnel to tap the mine. This claim is no doubt very rich.

BLACK ROCK.—This mine adjoins the Murray, and is down about 45 ft. This mine is owned by Lee Pader and others, and the rock improves in quality as they descend. The miners are engaged in running a tunnel to give an outlet for the water in the mine.

LITTLE ROCK.—The Little Rock, just above Black Rock, owned by Hunter & Berry, is down only 0 ft, with an 18-inch vein of good looking ore.

NOTES.—The Last Chance is down 25 ft on first-class

ore. In addition to these there are several other locations of more or less value. These mines are owned by poor men, consequently the progress made in developing them is not rapid.

SIERRA.

ANTHUP MINE.—*Mountain Messenger*, June 26: An interest in this mine has been sold to parties who are making arrangements to push work on the same. This claim is located west of the famous Brush Creek mine, and immediately adjoining it. Some very rich specimens have been taken from the ground, and there is a tunnel in about 400 ft. The new owners will put on 3 shifts at once and push work, and 400 ft further, it is believed, will tap the ledge.

NOTES.—Work has been commenced on a tunnel in Caribou ravine. It is about 40 ft higher than the tunnel started there a few years ago. We were misinformed in regard to the stoppage of work on the Savage Placer tunnel. There has been no cessation of work, and the tunnel is going ahead at a fair rate of speed. It is reported that the Black Jack mine, Jim Crow canyon, began crushing rock last week. The property is owned by Senator Jones and Budd Noble.

TUOLUMNE.

BLUTHUR CON.—*Independent*, June 20: This mine is situated on Deer Flat, 1 mile from Groveland, and is 1 of the early-cropper mines in this district. It is as promising as any in the country, judging from the present showing—a vein of good milling ore, averaging 5 ft wide; slate wall. A tunnel is in the vein several hundred ft. It is more than probable that a new mill will be built the coming summer to replace the one burned last summer.

MOUNT JEFFERSON.—This mine is near the town of Groveland, and is fitted up with a 10-stamp mill, steam power and having all the latest improvements for the reduction and saving of water. Also classification work being done on a small scale. The sulphurets carry 90% of the yield of gold per ton of the ore, and is consequently classed more particularly a sulphureted mine. The vein is found to widen out as the works are carried down, and at the lowest point reached, the 250 level, it swells out to something like 20 ft or more. The works of late have lain idle, but the machinery, etc., is being refitted, and the mill will be started up within a few days and a force of hands placed in the mine.

TRINITY.

RED HILL.—*Independent*, June 26: In company with E. P. Dany, Esq., we took a trip to Red Hill last Monday, and noted many changes made in the several years since we visited that section last. While it is one of the best mining regions on the coast, the limited supply of water keeps it back and prevents much mining which would otherwise be done in the district at an immense profit. The claims now being worked—all for which any water at all can be obtained—are paying largely, and the present season bids fair to prove a most profitable one for the owners.

NOTE.—Water is plenty; miners continue to sluice and are happy. Cold dust is coming in slowly, the bulk being reserved for the grand, final clean-up a month or so later.

NEVADA.

WASHOE DISTRICT.
BECKER.—*Old Hill News*, June 30: The north drift on the 3000 level has been advanced 20 ft during the week, making its total length 103 ft from the incline. The face is in very hard ground. The south drift, on the same level, is now in 44 ft from the incline. The face shows porphyry and some quartz, and one for the owners.

HALE & NORCROSS.—During the past week the incline has been sunk and timbered 22 ft; total depth, 301 ft below the 2200 level. The hoisting engine has been repaired and work is progressing as usual. Ninety-eight tons of ore have been hoisted from the 2100 level. Average crop samples, \$46.30.

MEXICAN.—On the 1000 level the joint Ophir east crosscut has been extended 28 ft. On the 2300 level are still enlarging and timbering the north drift. On the 2500 level the joint Ophir upraise is being enlarged to the size of the winze. The joint east Ophir crosscut on this level has been extended 30 ft, and the north drift 61 ft.

OPHIR.—On the 1600 level the joint Mexican east crosscut has been extended 40 ft. On the 2500 level the joint Mexican upraise is being enlarged to the size of the winze. The north drift on this level has been advanced 33 ft, and the joint Mexican crosscut on the same level has been extended 42 ft.

UNION SHAFT.—The 2500 station will be completed this week, and a drift will at once be started from this point for the Sierra Nevada incline. As soon as the pumps are working to the 2500 level, the Sierra Nevada incline will be drained and a drift will be started to meet the one from the Union shaft, 2500 station.

SAVAGE.—The main incline during the past week has been repaired and retimbered 31 ft, making 131 ft above the 1000 level.

UNION CON.—No. 2 winze on the 2400 level is making only 1½ ft per day. The ground is very hard and there is a strong flow of hot water. The winze is being timbered closely. The northwest drift on the 2400 level has been extended 50 ft. The south drift on the same level has been extended 17 ft.

SIERRA NEVADA.—As soon as the Union pumps are working to the 2500 level the incline will be drained and a drift will be started to connect with the one coming from the Union shaft 2500 station. The north drift on the 2400 level is out 912 ft and is still in encouraging vein material.

CALIFORNIA.—During last week 477 tons of ore were extracted and sent to the mills from the stopes on the 1600 level. The assay value of this ore was \$37.51. There is no diminution in the ore product. The north drift on the 2300 level has been extended 15 ft.

CHOLLAS.—On the 2400 level the south drift is being cleaned out and it is expected that the diamond drift will be started to-morrow. There is so great a flow of water that the drift cannot be advanced. Prospecting is therefore confined to diamond drift operations.

AURORA DISTRICT.

PROSPECTS.—*Esmeralda Herald*, June 26: This property has been secured by Cov. Blasdel. Work for the past week has been in advancing the tunnel crosscutting the ledge. Eight ft has been accomplished, making the entire distance 90 ft—all the way through ledge maker. A shaft is also being sunk, and is now down a distance of about 80 ft. The ore in the tunnel shows considerable gold, and in places can be seen plainly with the naked eye.

ESMERALDA.—Work was commenced on this well-known mine last Tuesday. The first blast that was put into the ledge threw out a mass of almost solid ore, estimated to run high up in the hundreds. The object of the work now being done is to show what the mine really is. **REAL D. MINE.**—About 20 ft has been accomplished during the week. The formation is considerable less broken, which is a good indication. About the middle of next week the work of putting in a plunger pump at the 650 station will be commenced.

CAMBRIDGE.—This property is situated about 3 miles north of the town of Cambridge. The ledge is about 4 ft wide, carrying good ore the entire depth of the shaft, which is now down about 100 ft. One thousand tons will soon be crushed as a test. It is thought the result will be about \$25 per ton.

THANSGIVING.—The south drift in the ledge has been extended 20 ft during the week in excellent ore, each shift of two men taking out an average of 4½ tons. The rock improves in quality as they go south.

GRAND TUNNEL.—The mass was extended during the week 13 ft, where they encountered 4½ ft of ore of excellent quality, and the whole face is still in ore.

COLUMBIA DISTRICT.

MOUNT DIABLO.—*True Press*, June 26: The main shaft has now reached a depth of 320 ft, and is making good progress for the fourth level, which will be reached about the first of next month, when a depth of 343 ft will have been attained. The sinking distance aggregates 3 ft per day. The east drift from the third level has reached a distance of 90 ft, and is now in a heavy body of clay on the west wall. The east drift on the second level is now

advanced 238 ft. There is still a distance of 25 ft to run to connect with the old works. This drift will connect with the ore bodies which the company opened up last fall. At this point the ore body will average 6 ft in width, and has been exposed eastward 120 ft.

SARATOGA.—The incline is now down 71 ft; from here a drift has been run 100 ft northwest, all of that distance in ledge material. This mine is looked on as one of the good properties of this district, assays from the surface reaching as high as \$84.

EAST MOUNTAIN BOY.—This mine has not been opened to any great extent yet, but during the week a ledge of \$71 ore, averaging 18 inches in thickness, was struck.

MOUNT FORT.—Ore is still being shipped to Belleville and the supply is kept fully up in the dump at the mine. The character of the ore is still of the same rich quality as noted heretofore.

LUCKY HILL.—The incline is still being pushed down as fast as possible and has reached a depth of 130 ft. The incline is now in plastic clay.

SILVER REEF.—Work is still progressing, and the find of last week bids fair to develop something of value. The ore, however, is low grade, assaying only \$40.

JACKSON.—The whim is ready for service, and will be started up to-day. In addition to the chloride now developed an 8-ft vein of ore is developed which assays \$30, \$30, \$41.00.

NORTH NEW ENGLAND.—The shaft is down 10 ft and is still in chloride averaging \$80. Work is still progressing fairly.

CHERRY CREEK DISTRICT.

STAR.—*Cor. White Pine News*, June 22: This mine has a 4-ft ledge of high grade ruby ore on the 650 or lower level, and also some rich chloride ore on the 300 level. A large percentage of the ore milled during the past month has been low grade, and considerable time was lost by the breakage of machinery, but the production of bullion has been fair.

NOTES.—Dr. Brooks is about to erect a 10-stamp mill on his property at Silver canyon, in the Schell Creek range. Assays made from samples brought in from the new discovery in Ruby Hill district, showed its value to be over \$1,000 per ton. Twenty men were put to work on the Teacup mine this week. They Grey Eagle mine is also working a full force of men.

EUREKA DISTRICT.

DEWITT MINE.—*Sentinel*, June 25: Mike Lyons shipped 41,415 lbs of ore to the Eureka Con. from the Dugout mine, which netted him, after paying all expenses, \$3,271.70. This is the first shipment out of 50 tons which has been taken out by 3 men during the past 4 weeks.

HAWKEYE.—Hensley & Stuart are still following the breast of ore which was struck in the Hawkeye several weeks ago, and have now about 40 tons of good ore on the dump.

DEADROCK.—Connection has been made in the Deadrock between the upper and lower tunnels, and a body of high grade ore has been exposed in the lowest workings which assay well up in the hundreds.

NOTE.—There are about 30 tons of high grade ore on the Bald Eagle mine, which will be sent to the Eureka Con. furnaces in a few days for treatment. The recent developments in the Banner are improving, and bid fair to lead to a large body of good ore. Frank Wallace has leased the 300 level of the Connolly mine, and is taking out a large quantity of flux, which is being shipped to the Richmond reduction works.

REMARKS.—*Mining Journal*, June 5: The new ore body in the end of the 200 main west drift, which is now called No. 16 chamber, is opening out very well; as far as explored it shows a length of 50 ft and 15 ft wide, and a height of 25 ft, with ore standing in the top, bottom and end, and it bids well to open out to a large ore body, and it being in new ground it is of great importance.

OSCEOLA.—*Independent*, June 26: The ore body which was found 40 ft above the 500 level, has widened to about 0 ft. The depth is not known of course; the ore has also improved in value.

OSCEOLA DISTRICT.

ONCEBET.—*Cor. White Pine News*, June 20: Operations on this mine have been going on about 10 days with an increased force, which has developed a vein of very rich gold ore. The new strike is a very important one, being much larger and richer than any heretofore discovered.

ITEM.—Quite an excitement prevailed yesterday among our placer miners, by the discovery of a north and south channel, which promises to be very rich in gold.

PHILADELPHIA DISTRICT.

BELMONT.—*Belmont Courier*, June 19: All work at the mine has progressed satisfactorily during the past week. Our drift between 200 and 300 levels was advanced 25 ft through a nice vein of quartz showing some fine ore. This raise from end of west crosscut was advanced 13 ft without any material change. The vein matter and quartz are getting harder, and I am in hopes of soon striking a solid ledge. The raise in north part of mine is showing good ore, vein 2 ft thick. Have advanced the same 23 ft.

BARRELOA.—Have cut through the stringers of quartz and struck solid ground, and when we get through this last we shall cut the back ledge in the north upraise we have advanced 15 ft. We run into a small break in upraise—quartz mixed with porphyry—but the mineral is coming in again. Wall smooth and perfect.

ARIZONA.

GLOBE DISTRICT.—*Silver Belt*, June 10: The Irene mine has a tunnel 330 ft long, at the end of which the ore was struck 250 ft below the surface. Besides the tunnel work, the vein was penetrated from the croppings by a vertical shaft, 57, 135 ft deep, and all in ore. Five assays of the ore ranged from \$58.11 to \$240.32, the average being \$98.

TOMBSTONE DISTRICT.—*Nugget*, June 26: The Grand Central hoisting works are now in active operation, and the material taken from the 3d level. The main shaft is now down 175 ft. At the end of the claim a prospect shaft is down 40 ft, from which there is a drift which will run 175 ft to the main shaft, and so far is all in rich ore. The croppings at the prospect shaft are identical with those at the main shaft, and the cut in that direction from the main shaft shows horn silver to a great extent. At the 3d level, ore is being taken out that assays high, and better. The 5d level they had been running in rich carbonate, but now it shows a fair percentage of gold. The total amount of work underground, so far, is 1,653 ft.

COLORADO.

Narrow Gauge Railroads.

[BY JOHN T. DAVIS.]

Fesling confident that a community is always ready to have laid before them any facts that pertain to the general good, I submit the following facts pertaining to the construction and advantages of a narrow-gauge railroad, and, to make it more conclusive, a short introductory of the rise and progress of the different gauges of railroads may be of advantage in the arguments that have led the commercial world to adopt a system that at first was a matter of supreme ridicule. During the

Early History of Railways in England
A great controversy arose among engineers as to the best gauge to be adopted; but, as all gauges were new and untried, the controversy was mere wordy warfare, and yet of sufficient importance as to engage the attention of such eminent engineers as Brunel and Stephenson, who took opposite sides and divided the profession into two hostile factions, who carried on a newspaper conflict known as the "War of Gauges."

The Brunels advocated the broad gauge with all the scientific force of weight and resistance explained in volumes of calculation; while the Stephenson became the champions of the narrow gauge, with a like amount of facts and figures to substantiate their theory. The Brunels were instrumental in having the seven-ft. gauge built, known as the Great Western, while the Stephenson had the Liverpool and Manchester built, a gauge only four ft. eight and a-half inches, which at that period was known as the narrow gauge. This controversy lasted for 20 years, and was decided at last by that most conclusive of all evidence, "experience." The broad gauge was changed to a standard gauge, and the Stephenson carried off the victory, and established a gauge that has since become the standard in the country where the roads were first introduced and the standard for our own country.

The Gauge Question in this Country.

Although we imitated our neighbors over the way, and tried the experiment of broader gauges than what is known as the standard, they have all proved financial failures, and not one is now left to exercise its influence on the hopes and fears of the unfortunate bondholder, but have all been changed to the standard gauge at a heavy outlay—the York and Erie costing its bondholders the nice little sum of \$8,750,000.

One of the first steps taken by its President, the Hon. H. J. Jewett, Esq., upon taking the Presidency, was to urge upon the English bondholders this outlay of capital before they could possibly expect to realize any interest on their investment. His long experience in railroad matters, coupled with his excellent judgment, was acted upon at once, and we now have the once famous broad gauge on a line with the other paying roads of the country, and with his skill as a railroad manager, the "York and Erie" will, from this time out, begin to pay its interest on its capital stock.

Why the Present Gauge was Adopted.

Stephenson's gauge was the result of accident or unexplained causes, and was occasioned by the putting together of the different parts of the locomotive, and was found to fit a gauge of four ft. eight and one-half inches, instead of four ft. nine inches, as was intended; and no one asked the question until a few years ago, "Why was the present gauge adopted?" The above is an explanation of a system that has become established, and that plays such an important part in the commercial world.

I will now ask the question, "Why has not a narrower gauge been adopted, or why was it not adopted while the controversy was going on as the best gauge for commercial purposes?" As man is somewhat of an progressive creature, his inclination was to make something better than what already existed, yet without stepping too far from the established custom, for fear of the opposition that would naturally spring up from so wide a difference—the country not being educated to the advantages of a gauge still narrower than the one in common use; but as many important improvements are brought to light and use by some circumstance, so it was left, too, for a circumstance to bring about the adoption of a narrower gauge than the one in common use.

The 22-ft. Gauge Railway.

The world-famed and initial narrow gauge of Festiniog, of North Wales, which was originally constructed, in 1832, as a horse tramway to carry slate from the quarries to a shipping point at Portmadoc, was nominally of a two-ft. gauge, although only 23½ inches in fact. This diminutive road was in constant use for over 30 years as a horse tramway, when a change of superintendents induced the owners to substitute a locomotive for the horses, and upon his recommendation two engines were built, weighing about 17 tons; these worked so admirably, and the results were so satisfactory, that it established the value of this mode of operating a railroad, and attracted the attention of Imperial Princes and Royal Commissions from Russia, France, Italy, Spain, Norway and Germany, together with engineers from the U. S. and Brazil, and the uttermost

parts of the earth; thither they flocked, wending their way among the famous Welsh hills to behold, and investigate, and criticize this wonderful miniature iron road that was doing the work of a broad gauge at a fraction of its cost. The novelty (for such was it considered at first) brought weekly visitors, until the manager, Mr. Spooner, wondered whether he was acting in the capacity of superintendent or showman. But this fact was so startling and conclusive that they stimulated the construction of other narrow-gauge roads on the continent, and the effect has been productive of much good to the commercial world.

The Average 3-ft. Gauge.

As a conservative medium has grown out of the many experiments of railroad building, we have adopted as a consistent gauge the three feet, and its growing importance cannot be over-estimated in this country, where railroads must be the forerunner of public improvement; and it has been left for us in the United States to demonstrate that we can penetrate the boundless prairie, or dive into the deep canyons, or climb the rugged mountain-side with our narrow-gauge railroad, and bring civilization and improvement after us, making the desert bloom with the fruit-tree and the valleys teem with golden grain—and this is the result of an experiment tried over 40 years ago among the barren hills of Wales. As it is my purpose to give some facts bearing upon this system, let us consider, first,

The Cost of Construction.

As nearly as facts have demonstrated, the cost of construction is as the width of gauge, except largely in favor of the narrow gauge, where the country is much broken or mountainous; and, taking an average of the cost of construction of several roads that it has been my pleasure of late to examine, we find the percentage of cost so much in favor of the narrow gauge that it remains a mystery why a wider gauge than three feet will be built at all, since the narrow gauge can do all the business the country can furnish. An average of the cost of construction and equipment does not exceed \$15,000 per mile, while the average of the standard and wide gauge is quite or nearly four times as much, or \$60,000. As this amount is a permanent investment, it is no difficult matter to make the comparison in favor of the narrow gauge, since the latter can do all the business the former can do and at a reduction of the cost of operating, besides saving the interest on \$45,000 per annum.

Practical experience has also demonstrated the fact that every inch added to the width of the gauge beyond what is absolutely necessary for the traffic of the road adds to the cost of wear and tear, and fixes a proportionate amount of dead matter to be kept in motion at the expense of increased weight of motive power and consumption of fuel, which entails a necessity of increased tariff and a consequent loss to the capital invested. The dead weight of trains conveying either passengers or merchandise is in direct proportion to the width of gauge adopted. In proof of this take the evidence at hand of any railroad in our country.

Comparative Cost of Operating.

A passenger car of standard gauge weighs, approximately, about 35,000 lbs., with a carrying capacity of 56 persons, making an average of 640 lbs., provided all the seats are occupied; but as that is not the fact on many roads, we assume that the number of passengers will average 35, making 1,000 lbs. of dead weight to each passenger hauled; while on a narrow gauge a passenger car only weighs 15,000 lbs., with a seating capacity of 36, making a dead weight of only about 400 lbs. to the head, and, making the same allowance for absentees, we have 23 passengers, or 15,000 pounds, thus effecting a saving of 40% of the dead weight, which can be utilized in transporting a paying product. And while this difference makes an exhibit largely in favor of a narrow gauge, the freight business is still more conclusive. The cars on the Denver and Rio Grande weigh less than three tons each and carry a paying load of eight to nine tons, being nearly or quite three times their own weight, while on the American standard it never exceeds one to one, and in many cases falls below even this standard. We have, then, the following advantages:

1st. A saving of the cost of construction, ranging from 40% to 75%, owing to the flexibility of the gauge in allowing the road to be built following closely the general contour of the country, and a consequent better gradient with lighter bridging and superstructure, a 30-lb. rail possessing sufficient rigidity to endure the pounding of the wheels of a rail 56 lbs. on a standard gauge.

2d. The less amount of dead weight actually moved in transporting the passengers and freight, amounting to 60%, and the advantage of utilizing this 60% in the transportation of paying commodities.

3d. The utilization of the difference in the quantity of dead weight in overcoming a heavier grade, enabling the road to be run through a more mountainous country without incurring the heavy expense of a wider gauge.

Other Advantages.

If we take an engine of equal power and weight, the gain is a large per cent. in favor of the narrow gauge. As an illustration, an engine with a 35x18-inch cylinder and 36-inch drivers will have a tractive power, on a level grade, equal to 1,460 tons, and will haul 1,064 tons of freight (the engine and cars weighing 400 tons), on a narrow gauge, while the same engine, with

the necessary cars, on a standard gauge, will only haul 900 tons of freight, as the engine and cars, unloaded, make a total of 566 tons, as against 400 on the narrow gauge, which is a loss of the tractive power of the engine of 162 tons, which has to be used as a motive power to transport the additional dead weight of the standard gauge, which, if applied to the transportation of merchandise, would amount to 18%, while the ratio of per cent. saved is greater on heavy grades—as the same engine will haul over an 80-ft. grade only 155 tons, while on a narrow gauge it will haul 182 tons, or about 20%; or take the same load over a grade of 95 ft. to the mile, so that the same steam power on a 3-ft. gauge, being no greater than on a standard gauge, its capacity is from 20% to 25% more, or an effectual saving of 25% in the consumption of fuel.

The Mistaken Idea.

So prevalent among American people, that a narrow-gauge railroad is limited in its capacity, needs but a single reference to convince them of the absurdity of this proposition. The Denver and Rio Grande, which has assumed greater proportions and had larger experience than any other, has not only silenced this clamor, but demonstrated that it is the kind of a road to build through a country that is only developing its resources, for not only has it met the requirements of trade, but has been the means of building up a country that would only have had a puny existence for years to come, and have remained an unproductive grazing country for years; but with its completion and advancement through the barren sand-hills and rugged canyons of Colorado, improvement has followed with rapid stride, and along its line can now be seen the handsome home of the farmer, with droves of cattle upon its thousand hills, bespeaking a life and prosperity that owes its happy and beneficial existence to the construction of that narrow-gauge railroad. And many special items could be cited of astonishing improvements brought about by the construction of this Denver and Rio Grande railroad, were it necessary; but the rapid development of that country, which owes so much to the construction of this road, is a part of the developed history of the country, and it remains for us to be benefited by the improvements of our neighbors.

The Narrow-gauge Roads of California and Nevada

Have been very successful, financially, and no one calls into question the fact that they have been the means of rapidly advancing the general prosperity of the country through which they pass; and such is the cheapness with which they can be built, and the small expense with which they can be operated, that every valley throughout the State will support one, and pay a handsome interest on the investment. The susceptibility with which they can be constructed and maintained in the most circuitous route renders it practicable to reach any mining camp of any note in the country, and long ere the mines have become exhausted, the whole line will be one continuous system of farms and vineyards, that will increase the percentage of profit on the investment.

Millions of capital are now seeking investment in some substantial enterprise, and no other presents so remunerative a field as the judicious construction of a system of narrow-gauge railroads, and no country in the world has such a diversity of interest commanding consideration; and the natural advantages of California, with its lovely climate, alluvial valleys, productive hillsides, and vast and inexhaustible mineral wealth—the latter only beginning to be understood and appreciated, and, like the narrow-gauge system of railroads, much has been learned of late that throws over the future of this business a halo of luster that sparkle far in the future.

In my negotiations with Eastern capitalists the past winter I was happily disappointed to find the prejudice that had heretofore existed against narrow-gauge railroads entirely gone, and they were quite willing to take the bonds of any well-located road with a fair amount of subscription applicable to the superstructure, and at a rate of interest that a few years ago would not have been entertained at all; but now, when Governments only hearing 4½% per annum cannot be had without paying two years' interest in advance, other enterprises having established merit, or even a promising future, find a ready support, with even a risk possible. As a people, we are rapidly growing rich, and the accumulation of capital is so rapid that the undeveloped resources of our country are only waiting the progressive spirit to lay them before the public or shape them into tangible form, and the means can be secured to build them into a permanent interest-paying and commercial enterprise, and a complete system of narrow-gauge railroads will certainly accomplish more for the country and the capitalist than most any other kind of public improvement.

Profits of Narrow-Gauge Railroads.

As the cost of the Denver & Rio Grande was \$13,500 per mile, divided as follows, cost of construction, \$9,520; cost of equipment, \$3,791, we take this road as a basis of our calculation to compare the results of building and operating. The interest on the above cost will only be, at 8%, \$1,080 per annum, and for 100 miles, \$108,000, and putting the operating expenses at 30% of the gross revenue of the road, and the wear and tear at 20%, the road would only be required to do a business of \$153,000 per annum to be a paying investment, an amount but little

above a well-regulated stage line, and to particularize:

20 passengers per day, at \$3.....	\$60
100 tons of freight, at \$5.....	500
	\$560

And for 313 days we have—560x313..... \$175,280
Leaving a net surplus over all expenses of... 17,280

It is needless to say that there is scarcely a valley in the State of California or Nevada that would not afford this amount of business, while on the other hand a standard gauge, costing four times as much, must necessarily draw its trade from four times its area of country, or secure some important connection that will give it a line of business that must be transported beyond its termini; and while the latter in many instances may succeed, and do succeed, the former could do the business much more remuneratively, and faster, and advance an enterprise that would develop the resources of the country in a much more rapid manner, while giving us an inter-State communication largely beneficial to our financial interests.

We now have nearly 4,000 miles of narrow-gauge railroads in our country, and the system is growing in popular favor so rapidly that parties seeking investments for their capital are quite willing to listen to the plans for constructing and the resources for sustaining a narrow gauge.

General Remarks.

Some time before the death of the Hon. J. Edgar Thompson, whose reputation as a railroad engineer is world-wide, and well and faithfully earned, in conversing and discussing the systems of railroads, and their future influence upon the general prosperity of the country, remarked that were he now building the branches of the Pennsylvania railroad he would make them 3 ft., instead of 4 ft. 8½ inches, his long experience satisfying him that the excessive amount of dead weight transported daily, at a useless expense of fuel and wear and tear, could and would be obviated by the narrow gauge. And how rapidly has his conservative opinions become the convictions of other distinguished engineers is evinced by the increased construction of so many miles of this gauge.

And after such a high endorsement, from a source that no one will question, it is not surprising that this system should take such strong hold upon the enterprise of our country, and give strength and power to a system of public improvements that will reclaim the "waste places of our country," and by a united assistance become a power in the land, that will make fruitful the valleys and hillsides of our uncultivated millions of acres.

Now that this system is doing so much toward the development of Colorado, and its success so well established, and such abundant evidence of the safety of the investment, let the enterprising citizens of this country take up this factor of public improvement, and an interest will be established that will place the prosperity of the Pacific Slope beyond the influence of sand-lot demagogues or the barings of discontented blatherskites.

The prejudice against narrow-gauge railroads has given way to a sound conversion of the benefits of the narrow-gauge system, and capital stands ready to meet us more than half way in the completion of this system and the permanent development of our country, and that which was started as a local convenience among the hills of North Wales bids fair to become one of the factors of our most permanent and beneficial improvements.

San Francisco, June 21, 1886.

MINING AT LAKE TAHOE.—As famous as Lake

Tahoe is as a delightful summer resort, it is likely to present new attraction to visitors from this coast at least. The Truckee Republican says from present indications it is likely to prove a great mining center. Already there is considerable excitement, and locations of claims are being made at a very lively rate. Some time ago a ledge was discovered about seven miles from McKinney's landing which prospected well, but the discoverers not having ready means to develop it, the matter was kept secret. Last summer considerable prospecting was done on the ledge, and its value proven. Out of one batch of 90 lbs. of rock, a button valued at \$4 was obtained, and the whole vein proved to be very rich. Lately an Eastern company of capitalists have taken hold of the mine and are going to erect machinery on it at once. The section about the mine is full of ledges, and they are being located by prospectors who consider themselves fully assured of a fortune. There is likely to be a flourishing mining camp over there soon. Gold-bearing ledges are known to exist in other places around the lake, and several parties have heretofore found black sand in paying quantities.

GOLD DISCOVERY IN OREGON.—It is reported that there has been a discovery of a rich gold-bearing quartz ledge in the vicinity of Grave (Leland) creek, Douglas county, Oregon, and that nearly 100 ounces of gold were pounded out of a small lot of ore. There has been more or less gold taken from this creek during the past 25 years.

At a meeting of the Virginia and Nevada mining company, held at Norfolk, Virginia, May 25th, it was unanimously agreed to push the Henry tunnel, White Pine, Nevada, through to the full extent of the location, 3,000 ft.

Charcoal Iron.

Charcoal, says the N. Y. *Mining Record*, is the ideal blast furnace fuel. More iron can be made from a ton of it than from any other. In spite of its great bulk more metal can be produced from a cubic foot of furnace room with this than with any other fuel. Its product is the strongest known. It is the only fuel that does not add impurity to the metal made, and the only one that requires no flux on its own account. Finally, to this list of its perfections must be added its monopoly of the mysterious alchemy of chilling, a phenomenon of which the world has taken advantage for a century, but really does not understand even at the present day.

There is a reason for all this train of excellencies, and that reason is necessarily included in the peculiar conditions of charcoal as a form of carbon and its adaption to the artificial conditions of the blast furnace. Charcoal being a fuel of maximum perfection, it is evident that the law of combustion, as a practical, as distinguished from a scientific question, is to be discovered by the study of its promiscuity. Something has been done in this direction. Berkinhino, Church and others have tried to point out the conditions and causes of its superiority, but much remains to be done. The vast economies which are every day reducing the cost of other irons, have not been applied to this, for fear of losing the valuable qualities which alone make the sale of charcoal pig possible at the high ruling prices. If we are to judge by what has been done in other departments of iron production, we ought to be able to advance to a cheaper manufacture of charcoal iron without losing any advantages of quality.

ENILE MINING IN SIBERIA.—The popular idea of the fate of prisoners sentenced to hard labor in the mines of Siberia is a somewhat exaggerated one. It is generally believed that a man condemned to work in the Siberian mines is virtually condemned to death; that when he descends into the mines he says good-bye to the light of heaven forever, being kept underground until he dies; and that living as he thus does, amid unhealthy fumes, death is not long in coming. A correspondent of the *London Times*, having heard these statements before he went to Siberia, appears to have taken some trouble to ascertain whether they are true or not, and, after many inquiries, "common fairness," he writes, "compels me to say that every one denied that there was any foundation for them." "Even," he continues, "the few Poles who spoke so bitterly of the Government did not bring this to their charge; nor did I meet any of the convicts who said as much." On the contrary, the silver mines were, so far as he could learn, worked on the 12, and sometimes even on the 8-hour system; while in the gold mines, which he himself visited, the men worked in summer from 6 in the morning till 7 at night, with intervals of rest for meals. In the coal mines, also, the men only worked for 12 hours a day, and an officer informed the writer that the amount of work allotted to each man per day ought to be got through by an energetic workman in about two hours. On the other hand, it appears that flogging is not infrequently inflicted in a barbarous manner in Siberia. At three stations, but apparently at three stations only—at Kara-Nicolaiievsk and Saghalien—an instrument called the "troichatka," or plait, is used. From 20 to 50 stripes are usually administered, though the number may be made a 100; and the writer adds that "when heavy numbers are inflicted, the punishment must be little short of an execution. Sometimes, in fact, the convicts do not recover from its effects."

A MONTANA MINE.—We learn from the *Salt Lake Tribune*, of June 17th, that the Boulder mine, of Boulder Co., Montana, is owned by J. P. Lawson & Co. of that city. Although it was discovered late in the summer of 1879, nothing was done toward its development until it came into the hands of the present owners, some time in February of this year, when a force of men was put on and three inclines started on the vein. These inclines were sunk to a depth of 50 ft., when they were discontinued and others commenced at intervals along the vein, the object being to ascertain the length of the ore chute, or chimney. Eight of these inclines have now been put down to depths varying from 20 to 65 ft., thereby proving the vein for a distance of 1,200 ft. The pay ore streak will average 8 ft. in thickness, carrying ore which yields from \$20 to \$500 in gold to the ton. The average has been placed at \$40, and we think this will not be found too high an estimate. The mine has now reached that stage of development to warrant the erection of a mill, and a contract was let last week for one of 20 stamps, to be running by the last of July. The motive power will be water, and it is estimated that the cost of milling will not exceed \$2.50 per ton. The outlook before the owners of this valuable property is exceedingly bright, and we are confident the near future will see them amply rewarded for their pluck and energy.

SHAD BREEDING.—Major Ferguson, of the Fish Commission, who shipped 200,000 young shad to California recently, is much encouraged by the result of his work, which is now about to close for the season. Over 12,000,000 shad have been hatched and distributed during the season, and the attention of the Commission will now be devoted to other varieties of fish. It is intended to extend the scope of the Commission by establishing a park for oyster breeding.

USEFUL INFORMATION.

Sand.—Its Origin and Varieties.

Sands are derived originally from the decomposition of the older rocks, either by the action of running waters or by the spontaneous decomposition of the rocks themselves. They are technically distinguished from dust by the fact that they sink at once to the bottom of water without leaving any sensible quantity in suspension. The decomposition of the rocks often gives rise to an agglutinating substance, which accompanies the sand and binds it together; but when acted upon by the waters it soon parts with such heterogeneous particles, and it arrives in a comparatively pure state in the beds of the principal rivers. This purity is lost as the rivers approach their embouchures; for the diminished velocity of the current allows the heavier particles to subside before arriving there. The water then only carries down the light earthy particles and the decaying vegetable matters which may fall into it, thus giving rise to the formation of clay deposits. The constituent parts of sands represent faithfully the rocks whence they are derived. Thus the granite rocks produce a sand the principal ingredients of which are quartz, feldspar and mica; the volcanic rocks are represented by sands in which lava, obsidian, etc., appear; the flat, soft-grained sand arises from the disintegration of the schistose rocks; the calcareous rocks, as might naturally be expected from their soft nature, are those which are least represented in the series, unless in the case of the silicious sands arising from the comminution of the flints, so plentiful in some of the secondary formations.

The partial and secondary revolutions of the globe have given rise to immense formations of sand in places where rivers have long since ceased to flow. The sand extracted therefrom is known under the name of "pit sand," to distinguish it from that borne down by the rivers, called "river sand," and from the "virgin sand," which remains in the places where formed, without in any way suffering the action of water. Pit sand is generally of a sharper and more angular grain than river sand, but in all other respects its composition is identical, excepting that it is occasionally stained by ochers. Practically speaking, clean, sharp, coarse sand is best, and makes the hardest plastering as a general rule, and it is safe to rely on river sand, the coarser the better, within reasonable limits. Lake sand is the same as river sand, and pit sand always makes good work when the sand is clean and coarse.—*From Chamber's Plasterer's Manual.*

THE HEART AS A MACHINE.—The heart is probably the most efficient piece of physical apparatus known. From a purely mechanical point of view it is something like eight times as efficient as the best steam engine. It may be described, mechanically, as little more than a double force pump furnished with two reservoirs and two pipes of outflow; and the main problem of its action is hydro-dynamical. The left ventricle has a capacity of about three ounces; it beats 75 times a minute; and the work done in overcoming the resistance of the circulating system is equivalent to lifting its charge of blood a little short of ten ft. (9.23 ft.). The average weight of the heart is a little under ten ounces (9.39 oz.). The daily work of the left ventricle is, in round numbers, 90 ft.-tons; adding the work of the right ventricle, the work of the entire organ is nearly 125 ft.-tons. The hourly work of the heart is accordingly equivalent to lifting itself 20,000 ft. an hour. An active mountain climber can average 1,000 ft. of ascent an hour, or one-twentieth the work of the heart. The prize Alp engine, "Bavaria," lifted its own weight 2,700 ft. an hour, thus demonstrating only one-eighth the efficiency of the heart. Four elements have to be considered in estimating the heart's work: (1) the statical pressure of the blood column equal to the animal's height, which has to be sustained; (2) the force consumed in overcoming the inertia of the blood-veins; (3) the resistance offered by the capillary vessels; (4) the friction in the heart itself. This, in a state of health, is kept at its minimum by the lubricated serous membrane of the pericardium.—*Scientific American.*

INOCULATING CHICKENS.—M. Pasteur, the French chemist, has presented to the Academy an important contribution to the subject of virulent diseases, with especial reference to the disease commonly called chicken cholera. He has made the important discovery that the germ of this disease can be artificially cultivated in such a manner that its virulence will be greatly lessened. By inoculating chickens with such changed or modified virus, the disease is controlled precisely as the virulence of small-pox is controlled by vaccination. The value of this discovery is manifest. Pasteur finds that the germs of chicken cholera increase with marvelous rapidity in a chicken broth, neutralized by potash and rendered sterile by a temperature of from 230° to 239° F. If the point of a needle be dipped into a virulent broth the prick of the needle will be fatal to chickens, but it produces merely an abscess in Guinea pigs. The virulence may be diminished by retarding the development of the germs, and inoculation does not then become fatal, but it produces a temporary disorder which, like vaccination, serves as a guard against subsequent attacks.

ON THE USE OF PLASTER OF PARIS.—The plaster may be made to "set" very quickly by mixing it in warm water to which a little sulphate of potash has been added. Plaster of Paris casts, soaked in melted paraffine, may be readily cut or turned in a lathe. They may be rendered very hard and tough by soaking them in warm glue until thoroughly saturated, and allowing them to dry. Plaster of Paris mixed with equal parts of pumice stone makes a fine mold for casting fusible metals; the same mixture is useful for encasing articles to be soldered or brazed. Casts of plaster of Paris may be made to imitate fine bronzes by giving them two or three coats of shellac varnish, and dusting on fine breuze powder when the mastic varnish becomes sticky. Rat holes may be effectually stopped with broken glass and plaster of Paris. A good method of mixing plaster of Paris is to sprinkle it into the water, using rather more water than is required; when the plaster settles, pour off the surplus water and stir carefully. Air bubbles are avoided in this way.

CARE OF MILK.—A writer in a recent number of *Nature* says that milk is especially liable to be affected by the atmosphere about it, whenever it rests in open vessels. In the cleanest pantry or larder, it gathers the effluvia of meat, cheese, onions, bread, fruit and such matters; the result being that it is soured and spoiled. In kitchens, nurseries, living and sleeping-rooms, closets, etc., the case is worse. Nature intended that milk should be drunk at once at its source; and it is very likely that exposures and delays impair its power of nutriment. Milk should be kept as much as possible in close vessels.

COLORING MATTER FROM CAMPHOR.—A valuable dye has been produced from camphor by Dr. W. H. Gregg, of Elmira, N. Y. The only color that he has been able to produce, so far, is yellow in a variety of shades, but he hopes to produce scarlet or carmine. The special features of the dye, aside from its novelty, are its brilliancy and the peculiar fastness of its colors. Boiling for hours in a strong soap solution barely turns the shade of cotton treated with the dyes. The colors will remain good even after the fiber has been destroyed.

GOOD HEALTH.

Checking Perspiration.

A Boston merchant, in "lending a hand" on board of one of his ships on a windy day, found himself at the end of an hour and a half pretty well exhausted and perspiring freely. He sat down to rest. The cool wind from the sea was delightful, and, engaging in conversation, time passed faster than he was aware of. In attempting to rise, he found he was unable to do so without assistance. He was taken home and put to bed, where he remained two years; and for a long time afterwards, could only bobble about with the aid of a crutch. Less exposures than this have, in constitutions not so vigorous, resulted in inflammation of the lungs, "pneumonia," ending in death in less than a week, or causing tedious rheumatisms, to be a source of torture for a lifetime. Multitudes of lives would be saved every year, and an incalculable amount of human suffering would be prevented, if parents would begin to explain to their children, at the age of three or four years, the danger which attends cooling off too quickly after exercise, and the importance of not standing still after exercise, or work, or play, or of remaining exposed to a wind, or of sitting at open window or door, or of pulling off any garment, even the hat or bonnet, while in a heat. It should be remembered by all, that a cold never comes without a cause, and that in four times out of five, it is the result of leaving off exercise too suddenly or of remaining still in the wind, or in a cooler atmosphere than that in which the exercise has been taken.

The colder the weather the more need is there, in coming into the house, to keep on all the clothing, except india-rubber or damp shoes, for several minutes afterwards. Very few rooms are heated higher than 65° when the thermometer is within 20° of zero, while the temperature of the body is always at 98°, in health; so that if a man comes into a room which is 30° colder than his body, he will rapidly cool off, too much so often, even if the external clothing is not removed.

It is not necessary that the perspiration be visible; any exercise which excites the circulation beyond what is natural, causes a proportional increase of perspiration, the sudden checking of which induces dangerous diseases and certain death every day.—*Hall's Journal of Health.*

ORANGES AS A REGIMEN.—A vast number of oranges are eaten by the Spaniards, it being, in fact, no uncommon thing for the children of a family to consume ten or a dozen oranges each, before breakfast, gathering them fresh for this purpose from the trees. Such wholesale consumption of what is commonly looked upon as a luxury, appears to have no unwholesome effect upon the system. On the contrary, the testimony of a late eminent physician authorizes the use of fruit ripe, fresh and freely as a trustworthy auxiliary in the treatment of chronic dyspepsia.

LONDON WATER.—In the *Macmillan Magazine*, Mr. Torrens, M. P., in treating of the water supply of London, describes the actual condition of an out-of-doors cistern in a locality near the Seven Dials. "A poor woman who had known better days, at a vigorous age and strong constitution, sickened and died; and the tank which supplied her only beverage was found to contain two inches of mud, the decomposing bodies of 14 rats, a bar of soap, two candles and many dead beetles." Even in the Mansion House itself, as an instance of what occurs in in-door cisterns in the houses of the wealthy, the civic cistern "was found to contain three-quarters of an inch of fungi-scrub at the top, and three-eighths of an inch of mud at the bottom;" while, "in a bottle of water on the Lord Mayor's table could be seen hundreds of nematoid worms." From cisterns thus situated, adds the *Building News*, probably nearly one-third of the inhabitants of London obtain their only stock of drinking water; and when we reflect on the liability of water to absorb germs and ferments without actual contact, and to become putrid under certain conditions in a few hours; when we remember also the untimely fate of the old lady in Mr. Torrens' story, we can hardly escape a shudder.

NERVE GRAFTING.—Dr. J. Gluck, of Bucharest, lately brought before the ninth congress of the German Society of Surgery of Berlin some interesting results of experiments in nerve grafting. He cut out a portion of the sciatic nerve of a fowl, and then removed a similar portion of the same nerve from the leg of a rabbit, and placed this in the leg of the fowl, uniting the two ends by sutures. The nerve united, and the paralysis caused, of course, by the excision of the piece of the nerve, was recovered from. He repeated the experiment, and exhibited the successful results, showing the fowls with full restoration of power. He was led to these experiments by the result of a case of nerve anura. Paralysis of the median had resulted from the extensive destruction of the tissue of the arm by gangrene. Dr. Gluck cut down on the radial nerve and found that part of the nerve was destroyed. He united the two ends by sutures, and the man regained the power of motion which he had entirely lost. Of course, the experiments of nerve grafting in animals, adds the *Lancet*, do not warrant the expectation that a similar result could be obtained in the case of the human subject. It is well known that the union and regeneration of nerves occur with greater facility in the case of the lower animals than in man.

IMPORTANCE OF SANITARY ENGINEERING.—The authorities of one of the largest hospitals in London lately took measures to ventilate all the drains and sewers in connection with their institution. Up to the time these alterations were made, pyæmia and erysipelas had almost driven the medical staff to despair. When the whole of the ventilation was completed, and as soon as the pressure was removed from the traps of the closets and lavatories, no fresh cases were found to occur. For months the hospital wards were free from both erysipelas and pyæmia. Suddenly, however, there was a fresh outbreak of these diseases, but it was noticed that the epidemic was confined to one of the surgical wards built apart from the main building, on the pavilion plan, and having only one story. Close investigation proved that the ventilation pipe in this wing had been stopped up by a careless workman. When this was remedied all traces of the epidemic disappeared.

D. J. SULLIVAN, a prominent builder of Binghamton, died May 22d, of malarial fever contracted at the Insane Asylum building, where he had been making alterations and repairs. Malaria from an old sewer that formerly extended underneath and through the center of the building is thought to have caused sickness of many of the men engaged on the work. Three of them died. How many other public institutions are in the same condition? We fear too many.

HEALTH OF PRIMARY SCHOOL CHILDREN.—A Massachusetts physician says that a healthy child may, perhaps, safely enter the primary school at seven years of age, but if nervous or inclined to talk or be restless in sleep, better wait another year.

LIMESTONE FOR DWELLINGS.—A Texan professor has written a pamphlet to prove that cities built of limestone are the healthiest in the world, and never much visited by malarial diseases, including yellow fever. The limestone is said to absorb carbonic acid arising from animal and vegetable decomposition.

VIGOROUS OLD AGE.—*London Nature* makes special mention of the fact that M. Chevreul, who is now in his 95th year, has begun his course on chemistry, at the Paris Museum of Natural History, with as much apparent zest and energy as when, 50 years ago, he entered on his duties.

DIPHTHERIA.—The benzoate of sodium has of late been so successfully employed in the treatment of diphtheria that physicians of prominence pronounce it almost a specific for that terrible disease.

MORTALITY OF MEN AND WOMEN.—In a report on the statistics of English mortality, Mr. Weldon states that for the last 30 years more women have survived to the high age of 75 to 80 than men. The latter suffer more from diseases of the lungs, heart and kidneys, and the lung diseases have latterly increased in England,

TABLE OF CONTENTS.

GENERAL EDITORIALS.—First Locomotives in America, 1. The New Test Mine, Colorado District, 4. The Week; Investing in the Mines of California; Ore Crushing.—No. 1, 8-9. The Forestry Inquiry; A National Monument, 9. Notices of Recent Patents; The Fourth of July in San Francisco, 12.

ILLUSTRATIONS.—The "Best Friend"—First American Built Locomotive, 1. Ideal Sketch of a National Washington Monument, 9.

CORRESPONDENCE.—Notes from New York, 2. Letter from the Comstock.—No. 2, 3.

MISCELLANEOUS.—Lead Patents Issued; Carp Culture; Skeleton Found in the Shaft of a Mine; Rich Discoveries on White River; Railroad Building in Arizona, 2. Narrow-Gauge Railroads; Mining at Lake Tahoe, 6. Charcoal Iron; Exile Mining in Siberia; A Montana Mine, 7. Exploration of the Big Horn Country; The Washoe Placer Mine; Gold Quartz Discovery, 10.

MECHANICAL PROGRESS.—A Wonderful Advance in Fuel Arts—Strong's Water-Gas System; Marine Engines; Make Your Own Tools; A Powerful Testing Machine; Avoidance of Vibration with Machinery; Machine for Working Metal, Stone and Wood, 3.

SCIENTIFIC PROGRESS.—"Evolution Admitted, What Then?" Astronomical; The Fossil Man; Microscopic Tests; Source of Muscular Power, 3.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 4.

MINING SUMMARY from the various counties of California, Nevada, Arizona and Colorado, 4-5.

USEFUL INFORMATION.—Sand—Its Origin and Varieties; The Heart as a Machine; Inoculating Chickens; On the Use of Plaster of Paris; Care of Milk; Coloring Matter from Camphor, 7.

GOOD HEALTH.—Checking Perspiration; London Water; Nerve Grafting; Importance of Sanitary Engineering, 7.

The Week.

Cool and bracing weather prevailed from the beginning to the end of June; indeed the uniform low temperature of the month was remarkable. It will prove beneficial to the grain that is maturing, and will be no less advantageous to the busy husbandmen in the field. Harvesting is now general, and there is complaint in some sections of the State of a scarcity of labor. Great activity is also showing itself in the orchards, and the product promises to be of excellent quality.

Reports from our multifarious exchanges from every State and Territory on the coast continue to herald unwonted activity in nearly every one of their numerous mining camps. There are reports of new and valuable discoveries, of energetic work, and of frequent sales of mining property. In Arizona the field of operation is extensive and lively, while all through the mining counties of California, and in many of the mining districts of Nevada, there are cheering signs of present and coming prosperity. In this State especially the outlook for a heavy product is highly encouraging.

Since our last issue the Board of Freeholders, elected by the citizens under provisions of the new Constitution to frame a charter for this city, has completed the arduous duty, and the voluminous document has been published in full. It will be submitted to the popular vote at a special election to be held September 8th. No citizen should neglect to give the charter a careful reading.

During the week intelligence has been received from Washington that several new money-order offices have been established in this State, as well as in the adjoining States and Territories; and also that two additional life-saving stations will be immediately constructed and properly fitted at designated points on this coast.

The national holiday, which this year falls on Sunday, will be commemorated on Monday; and in another column we have set forth the preparations for its celebration in this city.

Investing in the Mines of California.

While the attention of Eastern investors is being just now strongly drawn towards Colorado and Arizona, California is not by this class being wholly neglected. There are at the present time a good many wealthy and enterprising non-residents traveling over the State examining for themselves as to the opportunities that may here offer for getting hold of mines, aside from those who are seeking this sort of information through the agency of others. Some of these are men who have made money speculating in railroad and petroleum shares in the East or in mining properties outside of California, and come here now in the belief that our mines will prove the safest in which to embark their means in the long run.

And in this thing they are probably right. California is essentially a gold-producing country, and there can be no question but mining for this metal must, by the more cautious and considerate, be preferred to silver mining, even though the latter may for the time being yield larger profits. The liability of silver to undergo sudden and extreme fluctuations in price introduces into the business of mining for that metal an element of uncertainty that cannot fail to prove highly distasteful to the more wary and prudent investor. The status of silver in the currencies of the world is, to be sure, just at this moment satisfactory enough; but there is no telling when it may suffer such depreciation in value as would operate very injuriously to the business of producing it.

Then, it may be claimed that California offers some advantages for carrying on the business of mining for the precious metals not common to any other country where this industry is extensively prosecuted; our climate is superior; life and property are here well protected. Our mining titles are little involved or exposed to be involved in litigation. Our mining districts are of easy access; are well supplied with wood and water, besides offering much good farming and grazing land. Our ores are for the most part, free and easily treated, while labor is almost everywhere cheap and manageable. In the multiplied forms of mining practical in this State some further advantages may be claimed as likely to arise to the investor, who, through the same, may to some extent be enabled to consult his means or convenience when about to engage in the business.

Again, California seems about entering upon a new era of mineral discovery. On every hand we hear of rich strikes and important finds being made within her borders, some of these occurring in the placers and some in the department of vein mining. While these discoveries have been scattered all along the main gold belt it is noticeable that some of the most promising have occurred in the more northerly counties of the State, which have heretofore been by outside capital almost wholly overlooked. And here it may be pertinent to observe that in these northern counties will be found many good opportunities for making investments, the mines there, second to none in the State, remaining comparatively undeveloped and virgin. The chances for obtaining desirable hydraulic properties are there especially good. On this point we speak advisedly and from personal knowledge. The field is not very broad, being confined mostly to the Trinity and Klamath rivers. But here the conditions are generally good, the gravel being of high grade, water in large supply and easily introduced upon the mines, with no where any trouble as regards outlet, disposition of debris, the occurrence of indurated cement, volcanic cappings, barren material or those other obstacles which so often hinder and sometimes entirely defeat successful hydraulic operations in the older and more central mining counties.

Even so far north as Smith river, in Del Norte county, there are said to be extensive deposits of auriferous gravel on which several hydraulic enterprises could probably be inaugurated without any very large expenditure and with a reasonable prospect of success. On the Klamath river some openings of this kind also present themselves, with as till larger number along the Trinity and its tributaries.

On this latter stream several hydraulic claims have lately been put in shape for active working, the money for this purpose having been furnished mostly by California parties. The house of Watson, La Grange & Gibson, of San Francisco, have within the past year purchased and equipped two properties of this kind on the lower Trinity, both of which are now making satisfactory net earnings. The gravel on one of these, the Taylor Flat claim, turns out at the rate of 65 cents per cubic yard. This, though three times as much as the average yield of the gravel in the older districts of the State, does not much exceed the average of that handled in Trinity county. And yet there are in this county, as above remarked, a number of localities that afford the very best inducements for parties having the requisite means to engage in this branch of mining.

At some of these places, as on Oregon mountain, the mines have been partially opened and are paying well for the amount of water brought upon them. With a moderate expenditure for increasing the water supply, their annual gross revenues, some \$50,000, might be quadrupled. The Dutton creek ground, lying a little further

south on the same mountain, shows under extensive prospectings a deep bank of excellent gravel. Being, however, in the hands of poor men, it has for years lain a dead property, though a very little money, comparatively speaking, would suffice to transform it into an active producer and place it on a paying basis.

Situate further up the river, adjacent to the town of Trinity Center, is a placer district that has yielded as much gold dust as any other of like area in the county. The conditions for prosecuting hydraulic mining are here supremely good. There is timber and water in superabundance, while the material on which to operate is present in endless quantity and seemingly of good grade. The dump is ample, the Trinity here, into which the mines outlet, being a sweeping torrent with a fall of several hundred feet to the mile. And yet there is scarcely anything that can be called hydraulic mining in progress anywhere in this district. A beginning has, it is true, been made in that direction, one of the most stupendous schemes ever designed in California having been set on foot. Thousands of acres of these gold-bearing gravel lands have been aggregated into one estate, and portions of it patented. Water franchises covering the entire flow of the Trinity and its numerous confluent have been secured. Ditches have been surveyed and partially constructed. Houses, shops and roads have been built, tools and stores brought on the ground, and, in short, every preliminary expenditure incurred necessary to the effective prosecution of the great work in hand. And with this much done the whole business has been suffered to rest; not because it threatened to prove profitless nor yet because the projector was unable to carry it on, but simply because he had meantime taken hold of a bigger job—the reclamation of a million acres of land on the Colorado—a job of more magnificent proportions than this mining enterprise on the Trinity, but which cannot like this be postponed without serious detriment to the fortunes of this would-be swamp land reclaimer. And so the completion of this equally beneficent and even more promising undertaking will, very likely, be put off from year to year, unless other parties having less money but more leisure can be found to step in and carry it through, as they might do to their own great advantage; for certainly the scheme would seem to combine all the elements essential to a great success. This estate comprises in fact everything necessary to the construction of two or three first-class hydraulic properties, the auriferous gravel being here measured by the square mile, while the water flow carries for a good portion of the year not less than 60,000 miners' inches. But this rich material lies unworked and this water runs to waste simply because they happen to belong to one of the rich men of San Francisco, who does not feel the need of turning them at once to practical account. And so of other good claims in these outlying counties which remain unimproved and little productive because the owners are either too rich or too poor to do anything with them.

Ore Crushing.—No. 1.

[Written for the Press by J. RICHARDS.]

The processes for extracting gold from mineral stone are divided into two branches—one ("mechanical") relating to pulverizing or crushing the stone, the other ("chemical") relating to the extraction of the gold from the pulp, sand or dust.

These processes, in so far as breaking and crushing the stone, not only for gold, but other minerals, are much the same, and for centuries past have received the attention and efforts of able engineers in all countries where mining is carried on, and it is a reasonable assumption that any general tendency to "types" of machinery traceable through all this country, has a good foundation in the working requirements.

In California the first experiments were extremely crude and far behind what the practice of other countries afforded at the time. The first stamps used were unsuccessful, and Chinese laborers were employed to break the quartz with hammers, stone-breakers not having come into use. The development of machinery was, however, rapid, and, as usual, in this country bold innovations were made, until an efficiency and economy was reached not attained elsewhere in the world. This development has been almost exclusively by experiment and observation, not to any extent by inductive conclusions or the application of what may be called "principles," so that an impression was left, and now exists that such improvements are all matters of accidental discovery and chance.

The result of this is an annual "crop" of quartz-crushing machines invented by all kinds of people. A tailor or shoemaker may conceive that he is as likely to invent a new process as a miner or mechanic.

Such experiments are not necessary or likely to do any good. The principles involved in the operation of stone crushing, qualified by past history of the art, furnish data enough from which to determine the merits and advantages of different methods as they arise.

The processes employed for reducing quartz are:

1. *Percussion*, by blows, represented by gravity stamps,

2. *Pressure*, represented by rollers, whether supported in axes or balanced by "opposite" pressure.

3. *Maceration*, by rubbing action between surfaces.

4. *Disintegration*, by attrition between particles or rapid heating.

These four types of machinery include all now in use or attempted use. From the beginning the whole tendency has been to percussive processes or stamps, and nearly all departures, perhaps all, from this method, have been from a misapprehension of the relations this method bears to others. Some of the conditions may be laid down as follows:

(1.) In stamping machinery the strains are not imparted to the framing, nor connected through moving joints, but are absorbed by the momentum of the stamps and their stems.

(2.) The moving joints, bearings and all parts subjected to abrasive wear are removed from the quartz, and are placed above it, so as to be fully protected and thoroughly accessible.

(3.) All surfaces subjected to wear, including shoes and dies, requires no skill in replacing, are inexpensive and not machine fitted. Shoes and dies, for example, go from the foundry to the mill, no part requiring preparation.

(4.) A stamp mill consisting of a number of independent and duplicate parts, none of which are subjected to dangerous strain, there is but little risk of detention by breakage. If one battery is stopped, others go on, or if one stamp in a battery requires repairs it is soon substituted from inexpensive parts at hand. Especial attention is called to this sub-division and duplication of parts.

(5.) There being no close running bearings nor other conditions that call for special skill, stamp mills can be operated by the cheapest labor, almost any part can be safely "treated with a sledge hammer," the miners favorite implement.

(6.) The machinery being as before said undivided and consisting of duplicated parts, the amount of work and the consumption of power is at control, if the supply of rock is wanting a battery can be stopped and the others go on; this is an important feature.

(7.) The particles of gold do not suffer from attrition or "tearing" as in other processes where a rubbing action takes place, and this tearing or maceration is always present in all machinery where the acting surfaces do not approach each other parallel.

Taking these conditions and comparing with other processes he will have in most cases the converse.

For example (1) moving or sliding joints near to or below the level of the quartz; (2) renewable parts that require machine-fitting, not to mention expensive material such as steel or chilled surfaces with attached parts that require fitting. (3) The machinery not subdivided, all parts depending one upon the other, so that anything broken causes detention. (4) Close running joints that move under pressure. (5) The framing or other parts having to resist the strains of the pressure applied to the quartz, and not vertically to be resisted by earth foundations as in a stamp mill, and inherent in the machinery, so to speak.

In short, the mechanical conditions point unmistakably to the results which experience has in so expensive a way brought about, and there can be no doubt in respect to the future use of percussive processes for reducing hard mineral stone. The "hammer," throughout ages, and for the whole history of mankind has remained the leading implement in comparison with which the lever, roller, wedge screw, and so on, are but insignificant devices. To exert a great force throughout a limited distance (the required conditions in quartz crushing) no mechanical expedient compares to a "hammer," and the stamp mill is but a form and application of this principle.

In respect to crushing or preliminary breaking, we may find the same agreement between principles and experiences.

Twenty or more mines in England with many in Germany and elsewhere on the continent, employ what are called Cornish rollers for breaking, but it is believed no such plant has been erected in Europe or here since the introduction of the American reciprocating stone breakers. The common conclusion is that revolving rollers, acting as they do continuously, with unlimited or extended surface, must far exceed the performance of any machinery with reciprocating action and small surfaces. The fact is different, because not counting first cost, which is three to one in favor of reciprocating machines, the actual performances are more rapid by the latter. This will be understood when it is remembered that the co-efficient of effect in such machines is as the area of the acting surfaces and the speed at which they approach and leave each other. The mistake in respect to rollers comes from confounding their circumferential velocity with the working one, that is, with the velocity at which the surfaces approach and leave each other in the working plane. The acting surfaces are but a narrow line, while the whole surface of the jaws of a reciprocating machine are acting, and their speed in a working plane is greater than that of rollers, so that after all the history of the two processes is but a development of principles that, from the first, admitted of plain inferential conclusions. In a considerable experience the writer has never met with a practical man who did not confound what may be called the working speed of cylinder or crushing rollers with that of their perimeter.

It may be remarked here that this same prin-

ciple holds good in respect to stamps, when the crushing surfaces have a parallel approach, while with rotary machinery the approach is not parallel, except on an imaginary line at the center. In fact a reciprocating stamp bears much the same relation to rotary pulverizing machines that a reciprocating breaking machine does to rollers, and the end of experiment will not doubt be but a verification of what might be learned in a less expensive way.

The disintegrating process is a new one, comparatively, and as the action is concealed by casing and the parts running at a high speed, there is less known of the "nature" of the operation than others that are more easy to investigate. Messrs. Whelpel & Storer, of Boston, Thomas Carr of England, with many others, have attempted the successful application of this principle, in mode of operating, to quartz crushing. On this coast also there has been very thorough experiments made as to economic as well as mechanical results; but so far as the writer knows all pointing to the fact that the attrition of particles one against the other is less than it is between the particles and the metal driving surfaces, causing a rapid wearing away of such parts, while the agitation, so to call it, of the material, must represent a great loss of power. The history of the disintegrating process by rapidly revolving "beaters" or vanes will no doubt fall into its natural place in manufacturing processes, most likely the pulverization of material not silicious or of a nature to cause much abrasion. Such machines have now conquered a permanent and useful place not hitherto supplied, but not in the treatment of hard mineral stone. Time enough has now elapsed to determine this if we take the general history of this process instead of special cases. The action on material, be it what it may, is but one of the conditions that must in this and all other processes: qualify ultimate success. A necessity for rapidly revolving journals near to and on the same plane with the material is a feature that alone might defeat in practical use any advantage arising from a better method of breaking silicious material.

San Francisco, June 7th, 1880.

THE FORESTRY INQUIRY.—We have already mentioned the expected arrival of Prof. C. S. Sargent, forestry expert for the census office, and his associates. Later information from the East gives the plans of the forest examiners with more detail. They will begin by visiting Kansas to study the tree distribution on the eastern edge of the prairie and plain region; then they will go through Colorado, and possibly New Mexico, to examine on the spot the heavy timber in the canyons of the western spurs of the Rocky mountains. The labor completed, they will proceed, via San Francisco, to Victoria, and thence southward through Puget Sound to Portland, Oregon; then south along the western flank of the Cascade mountains to Roseburg, Douglas county, Oregon, where the party will make their headquarters for some time in order to examine the peculiar and little known forest vegetation of that region. Thence south again to the Mt. Shasta country, in northern California, where so many of the peculiar California trees were first discovered by Douglas and Jeffrey. From a botanical point of view the stay at Roseburg and in the neighborhood of Shasta will probably be the most interesting. The party will visit the great forest of Sequoias at the head of the Kern river in the southern Sierras. In Kansas and Colorado Mr. Sargent will be accompanied by Mr. Robert Douglas of Waukegan, and from Salt Lake westward by Dr. George Engelmann of St. Louis and Dr. Parry. The two latter, who are officially connected with the investigation, will pass the next winter in southern California, and return East by way of Arizona and New Mexico in the spring.

In Ophir canyon, near Franktown, Nev., Price's reservoir gave way on the evening of June 27th, and the rushing water carried everything before it. Three miles of flume and one house were destroyed. The railroad bridge was carried away. The tailings at the old Ophir mill were swept away, and the mill that was working them there will close. Happily no lives were lost.

RECENTLY in the Court of Common Pleas in New York, Judge Van Hoesen decided that a seat in a stock exchange was not property—that is to say, it is not property in the sense that would render it subject to levy for ordinary debt.

Letter From the Comstock.—No. 2.

EDITORS PRESS:—There has been little or no change at the North End since my last letter. The magnitude of the work makes progress necessarily slow, as the machinery being put in is of colossal proportions. All this work is not being done for the simple purpose of prospecting. The managers know that they have a mine there, and although they are showing it very slowly they will show it up eventually, and when the time comes Flood will co-operate with Mackay in sending the boom along. There is now no secrecy regarding the operations in Union and Sierra Nevada; any one can go there

A good story is being circulated around among the mining men here regarding the Alexander mine, which Lucky Baldwin recently visited. Charley Goodwin, of the *Enterprise*, visited the property and agreed with the owners to sell it to Sharoe. Goodwin then had a talk with H. M. Yerrington, Supt of the V. & T. R. R., whom he thought would be a good man to broach the subject to Sharon. Yerrington seeing an opening, concluded he would get the credit himself of selling the mine, and so sent Strother, of Virginia City, to take a look at the property. As the owners were anxious to sell it to Sharon through Goodwin, or any man he might authorize, they fought shy of Strother and showed him the poorest places. He went back and reported it a humbug. Sharon declined to

A National Monument.

The coming of the nation's favorite holiday, the Fourth of July, makes it timely to allude briefly to themes fit to call forth the patriotic flow. The year 1880, the country over, gives many promptings to national pride, and it is probable that Independence Day will be celebrated with unusual rejoicings and gratulation. There is a spirit of progress and prosperity abroad in our industries. The depression born of disorganized affairs resulting from the great conflict, seems now to have wholly passed away; and the people now stand with all the glories of the past to urge them on, and the free field of the future before them in which to win their victories in industrial, social and scientific advancement. It is a good time to review in mind the history of the republic, the glorious deeds of the early patriots, the priceless gifts of later heroes, and to picture the growth of this coming generations. If the results of such studies do not kindle the flame of patriotic pride in the heart of an American, such a one must have a soul so dead that no thought of greatness can awaken it.

We have chosen as an illustration appropriate to this time, an ideal sketch of a monument to the memory of Washington. This design is intended by the artist to fitly embody the idea, not alone of the majesty of the character of our country's father, but to typify the growth of the principles which he held as the corner-stones upon which to found a nation. It must be remarked that such a monument as yet exists only in the artist's drawings, but it is put forth to the view of the people as something worthy of their study, in the hope that some future year may see it, or something like it, hewn from enduring marble to remind coming ages of the veneration in which the great founder of the republic is ever to be held in patriotic hearts.

As most readers are aware, there is already a monument to the memory of Washington in progress of construction at the national capital. Of this, it may be briefly said that it was commenced in 1848 by an association incorporated by Congress. After an expenditure of \$230,000, raised by voluntary subscription, the monument came to a standstill for 20 years. Thus for a score of years it stood an unfinished column of 174 ft. in height. By act of Congress, passed in 1876, appropriating the sum of \$200,000, this monument is to be finished, and will form a lofty and imposing plain obelisk, 70 ft. square at the base and 470 ft. high. It is constructed of great blocks of crystal Maryland marble, lined with blue gneiss stone, and while simple and majestic in form, without attempt at ornament, will constitute a mausoleum that will last for ages, erected by the people of the whole country to its greatest citizen on a scale worthy of the nation.

It is the design of the artist whose work we present on this page, to have the imposing plain obelisk which we have described, serve as the central column of the majestic yet richly ornate structure shown in the engraving. It will certainly be more impressive to the average mind to contemplate a structure of this kind, upon which may be carved the history of the country's progress and the ideal embodiments of the principles for which we contend, than to view a bare shaft, which, no matter how much imagination may adorn it, is still but a vast factory chimney and barren of grace and beauty. It may be that some generation which is to come after us, will take this plain shaft which we shall build, and thus develop from it a monument which shall be more worthy of our country's progress in enlightenment and the science of government.

To the future then this design for a national Washington monument is commended in the hope that ere long it will pass from paper to the enduring stone, and stand perhaps a thousand years in memory of the "Father of His Country."

NORTH BLOOMFIELD MINE.—This great grave claim in Nevada county is one of the conspicuous features of California mining. The works of the company were visited lately by a representative of the *Herald*, who has furnished some interesting facts respecting its operations. Over 100 men, nearly all white, are employed, and nearly 4,000 inches of water are used in the daily washing. The gravel is said to be very rich in the present workings, and the property is in a prosperous condition—in fact, it is in bonanza. Preparations were under way for a blast of 24,000 lbs. of Judson powder,

IDEAL SKETCH OF A NATIONAL WASHINGTON MONUMENT.

and see every drift and cross-cut that is in existence. There have been rumors breathed about a diamond drill penetrating a body of ore north of the Sierra Nevada winz. No such drill has been used except to prospect for water. John Mackay is now striving to carry the Comstock on his shoulders, and in September he will lay aside his house and lantern, and go to Paris for a rest of two years. Those who are in a position to know, assert that before leaving he will put things in such a condition that the heirs will stop growling for a spell, and the bulls will feast in the clover fields of the North End. I consider this information pretty accurate.

Mackay has said that he would not quit the Comstock until he could leave it in good shape, and his determination to leave it in September for Paris gives some the hope that he has calculated on being able to open up the North End before that time. You can at least depend upon the fact that he will never leave it in the lurch.

huy. He could have got the mine for \$750,000, and now the property is offered at \$2,000,000, and not a cent less. When Sharon saw Baldwin in San Francisco and learned what a trade he had lost he is said to have made the air thick with rosy allusions to him.

Since my last letter there has been serious talk of a reduction of wages to \$3 above the tunnel level. The *Enterprise* says that the Miners' Union will do nothing about the matter until the capitalists put up low-grade reduction works. Now what assurance have the capitalists that the Miners' Union will agree to reduce wages after these works are erected? Let the miners agree to accept \$3 a day above the tunnel level and the reduction works would be erected in short order. The Union, however, declines to say what it will do, and no one cares to take risks in the proposition, nor will any one until something definite is arrived at.

HARD DRILL.

Exploration of the Big Horn Country.

Gen. Phil Sheridan three years ago made a rapid personal detour through a portion of the unexplored regions watered by the Big Horn river and its tributaries, says the *Pioneer Press* of June 3d, and he was deeply impressed with the necessity and importance of having that country more examined than was possible by the few military escorts that have threaded the passes of the Big Horn mountains. The few white men that have had the opportunity of seeing the lay of the country, are strongly of opinion that it is a land of gold, as well as rich in soil. The Big Horn, the Powder and Tongue rivers all have their sources in the latitude of Milwaukee, and traverse to a region that is several times larger than the State of Pennsylvania, about the geography and general character of which little is known, except the climate is mild, the valleys rich in grasses, and the hills filled with minerals.

Gen. Sheridan, in view of these circumstances, has ordered Lieut. William F. Clark, of the Second cavalry, now stationed at Fort Keogh, to form a party of 15 men, with half a dozen or more Indian scouts all to be mounted and abundantly provisioned, and to proceed on an exploring tour up the Big Horn river. Of course, the route to be pursued and the exact nature of his instructions have not been divulged by Lieut. Clark, but it is understood that the region to be more particularly explored has been mapped out, and will be thoroughly examined and described.

The Indians have heretofore held control of the great divide from which spring the great tributaries of the Yellowstone and the streams that flow southward into the Platte, and even the most adventurous miners have not succeeded in penetrating the Big Horn mountain ranges. But the Indians have of late become less troublesome, the hostile Sioux having sought new hunting grounds, and now is a good time to ascertain what ground there is for the general belief that the hill and valleys abound in the precious metals. It is claimed that "color" has invariably been found in the sands of the streams that issue from the mountains, and wherever "color" is discovered by the cursory observer, it is assumed to indicate that rich mines are not far away.

Col. Henry W. Farrar, of Chicago, who accompanied Gen. Sheridan on the tour from the Union Pacific railroad to the Yellowstone, has been selected as one of the observers that will make up Lieut. Clark's party, and he reached St. Paul, June 3d, on his way to Keogh, from which point the expedition will start in a short time. Col. Farrar will leave St. Paul immediately for Bismarck, where he will probably be able to secure a steamer, as information has reached St. Paul that the Yellowstone has risen three feet recently, and hence, no difficulty will be experienced in making a rapid and pleasant trip from Bismarck to Fort Keogh. Lieut. Clark is eminently capable of performing the important work committed to his charge by Gen. Sheridan. As a soldier he has been tried on more than one occasion, in which he has won distinguished honor, but his ability as a military commander is scarcely less than his capacity as a leader of a scientific expedition, for which his varied intellectual acquirements exactly fit him. The result of his tour of observation and investigation through the wilds of the Big Horn mountains during the coming summer will be watched with unusual interest.

THE WASHOE PLACER MINE.—Word came in yesterday, says the *Territorial Enterprise* of June 23d, from this mine, situated in the foothills of the Sierras to the westward of Washoe lake and to the southward of Slide mountain, that the shaft has attained a depth of 107 ft. The bottom is still in gravel showing some gold, and some water is beginning to come in. The parties concerned in the enterprise have shown regular bull-dog perseverance. A heavy rain at one time caused their shaft to cave from top to bottom when it was 90 ft. in depth. Their last trouble was an iron boulder so big that the full size of the shaft was blasted through it. This brought them to a depth of about 100 ft. The big boulder and the water now coming in causes them to believe that bedrock is not far away. Some 20 years ago a great deal of coarse, smooth gold (regular California lead gold) was taken out of a little ravine that heads in the hill whereon the present shaft is being sunk. The gold in this ravine was undoubtedly an overflow from a large channel in the hill. A great deal of work has been done at various times at running tunnels and sinking inclines and winzes in search of the old channel, but the present owners are the only parties who have shown much industry and courage. It is likely that when they get to the bottom they will find drift diggings—diggings in which all the gold lies on the bedrock and in 3 or 4 feet of gravel just above it.

MINE LITIGATION.—We learn from the *Bodie Free Press* that litigation is talked of between the Jupiter and Bodie mines to quiet title to the ground being worked by the former company, which by many is considered the most valuable in the district. The Bodie claim the ground under an old placer location which they purchased two years ago, and the Jupiter held it under quartz locations of undisputed age. It is stated that papers have already been filed in the United States Circuit Court at San Francisco.

GOLD QUARTZ DISCOVERY.—We are informed by the *Amador Ledger* of June 19th, that a prospector named Thos. Earhart discovered recently in the vicinity of Black gulch, about three miles south of Jackson, a bunch of quartz carrying a large percentage of gold. The quartz is unlike anything met with along the mother lode. It is much darker in color, and heavier than the whitish rock which abounds on the main lead. A glance is enough to convince anyone posted in such matters that the ore is largely composed of iron and other rebellious metals. Probably it could not be worked to advantage by the ordinary mill process, but would have to undergo a thorough roasting, preparatory to crushing. Its richness in gold, however, is beyond dispute. Specks of yellow metal are visible all over the samples of rock which we saw at the store of Ginocchio Brothers. The lowest estimate places its value at \$300 per ton. A small parcel was burned and pounded in a mortar, and yielded at least at that rate. Samples have been left with the assayer of the Zeile mine, but no return has been received as yet. The size of the ore-body cannot be stated at present. Indeed, no regularly defined ledge appears, but the discovery is in the shape of a hunch or pocket. Walls, however, are plainly discernible on the surface, the distance between them being given not less than 30 ft. Since the discovery was made a rush to locate claims has resulted. All the ground north and south for some distance has been taken up. The lead—if lead it should prove—is on a direct line with the Gwin mine, and the opinion is held in some quarters that it is a part of the same gold-bearing vein.

TO HARDEN STEEL CUTTERS.—Take a bucketful of clean water, and add a gill of vitriol; stir up well, and bottle for use. This will last for years, if kept corked up only when using it; put your cutter on the top of a piece of sheet iron, and when properly red drop into the liquor. This when taken out will be as hard as flint. Blaze, and let down to a purple for cast steel.

Canadian Patents for U. S. Inventors and Patentees.

One Patent now Embraces all the English Provinces in North America, including the Canadas and British Columbia.

It is only recently that the Canadian Government has granted patents to United States citizens. In consequence hereof the many immensely valuable inventions patented in this country are now patented in Canada. Patents are much sought for and are readily disposed of at fair cash prices. In our country about three-fourths of all manufacturing is based upon patents, especially in the New England States no manufacturing business of any consequence is started without being protected by such. Our neighbors across the border have not been slow in observing and learning that inventions and patents are the foundation of all prosperity in manufacturing purposes. Hence all our patents for labor saving and agricultural machinery and innumerable improvements in home comforts meet a ready market in Canada. Inventors and Patentees should therefore not delay to secure their patents in Canada; many good inventions are already pirated by Canadians, who, against law and right, appropriate United States inventions and have them patented in their own name. After a patent is granted it is extremely difficult to prove who is the first and original inventor. Therefore inventors and patentees to be safe, you will have to secure your patents in Canada without delay. We have facilities for securing Canadian patents second to none. Our charges for securing Canadian patents are about \$65. A model is required.

Inventors and patentees! do not delay and lose your opportunity. Things may change. With model and description of your invention remit \$25, and we will prepare all drawings and documents and forward them to you for signature. In about 30 to 50 days we can return your Canadian patent.

DEWEY & CO.,
Patent Solicitors, S. F.

Five sizes are made to suit the dimensions of different papers, viz.: 13, 22, 26, 30 and 34 inches, inside measure.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the way and wherefore. It contains 155 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3.00 coin, postage free.

SAW MILL MACHINERY.

Automatic Slide Valve, Universal Automatic Corliss and Cheap Hoisting ENGINES and BOILERS.

TATUM & BOWEN,

329 Market Street, 3 Fremont Street

ST. DAVID'S.

A FIRST-CLASS LODGING HOUSE.
CONTAINS 113 ROOMS.
715 Howard St., near Third, San Francisco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms. Gas and running water in each room. The floors are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 6 A. M. to 7 P. M. Hot and cold baths, a large parlor and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from \$2.50 upwards.

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

OXYGEN.

What is it? Everybody knows it is as essential to life as food itself. Yet when people are ill for the very want of revitalization through respiration, they dose themselves with drugs and bitters to the effect of demoralization! All Invalids should read Dr. STARKEY & PALEN'S (Phila.) *Treatise on Oxygen*, which is sent free to all who may ask for it. The subject is worthy of investigation. References to physicians in San Francisco, who use and prescribe Compound Oxygen in practice. As prepared for home use (conveniently sent to any address) it may be obtained of H. E. MATHEWS, 606 Montgomery street, S. F., upon the same terms as furnished by Drs. Starkey & Palen, Philadelphia, Penn. Complete instructions with each package.

Educational.

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

Machinery.

GOLD AND SILVER Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorinating Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafing, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,550.

We construct Mills with Stamps weighing from 350 to 600 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

MOREY & SPERRY,

No. 145 Broadway, - NEW YORK.

Important to Mine Owners and Cities.

— THE — Dodge Rock Breaker

CHALLENGES THE WORLD

To produce as good a machine. Sold at one-half the price of others, and guaranteed not to break.
Rock Breaker and Cornish Rolls Combined.
Rock Breaker and Pulverizer combined in one machine for pulverizing very fine.

Furnaces for chloridizing and desulphurizing ores.
Concentrating Jigs and Slime Machines for concentrating Gold, Silver, Lead and Copper Ores.

Amalgamators, and plans for working ores by the various processes. Address

M. B. DODGE,
Care of Prescott, Scott & Co., San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,
Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, sash, Mulay, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.
It is with pleasure that we publish the following from prominent Architects in this city:

Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welch, P. Huernie, John Marquis, E. McDougal & Son, Wm. Mooser, Wm. Curlett, Meeker & Banks, W. C. Hoagland, S. & J. Newson, B. Hendrickson.

How to STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes before the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

Dewey & Co. { 202 San- } Patent Agents

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING JUNE 22, 1886.

229,109.—DRYING APPARATUS.—E. F. Ely, Santa Rosa, Cal.
229,035.—BRECH-LOADING FIREARM.—W. R. Finch, Eureka, Cal.
229,036.—NEWSPAPER FILE.—W. C. Fitch, Sacramento, Cal.
229,040.—GRAFTING TOOL.—C. W. Hoyt, Petaluma, Cal.
229,144.—BOOT AND SHOE.—P. Kelly, S. F.
229,147.—GATE.—F. W. Lamb, Hydeville, Cal.
229,181.—TRACE CLEARER FOR MOWER.—W. Priudle, Santa Clara, Cal.

List of English patents applied for by Pacific Coast inventors:

447.—EXPLOSIVE COMPOUND.—M. Tishner, S. F.
458.—EXTRACTING METALS FROM ORE.—A. C. Tichenor, 685, —UMRELLA.—D. Harris, S. F.
778.—BED.—J. H. Archer, S. F.
1,162.—VALVE.—W. Wilson, Oakland, Cal.
1,216.—PHOTOGRAPHS.—E. S. Molera and J. C. Cebrian, S. F.
1,217.—PHOTOGRAPHS.—E. S. Molera and J. C. Cebrian, S. F.
1,280.—BEER.—A. J. Spencer, San Jose, Cal.
1,583.—CHROMOMETRIC MOTOR.—E. S. Molera and J. C. Cebrian, S. F.
1,620.—VESSEL.—J. S. Taylor, S. F.
1,669.—BOILERS.—E. S. Molera and J. C. Cebrian, S. F.
1,752.—ICE MACHINE.—C. C. Palmer, Oakland, Cal.
1,756.—PIPE LAYING APPARATUS.—E. M. Hamilton and C. N. Earl, Los Angeles, Cal.
2,192.—FIREARM.—A. Schneider and T. Elliott, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

BUTTON.—Elkan Shrier, 201 Montgomery street, San Francisco. This invention relates to certain improvements in that class of buttons in which an independent detachable disk and shank are employed to secure the button to its place, whether it be a sleeve or collar button, or a button of any other form which may be employed upon coats, pants and other articles of wearing apparel. Various devices have been employed to secure the button and disk together, and in some cases the shank has been notched at a point where it enters the button, and the catches by which it is held in place are loosened or released by means of projecting ends of arms which are compressed or forced inward for the purpose. This invention contemplates the employment of a button having a hollow sleeve projecting outward from its center and lower side, and adapted to receive a pointed shank which is rigidly secured to the securing disk. Small holes are made in each of the sides of the shank, and a holding pin or bolt passes through the side of the hollow sleeve at a point where it will just enter one of the holes in the shank, when the latter is forced into place. A spring holds the pin in, and a small head upon the edge, or beneath the button, may be used to retract the pin and release the shank when desired.

BOOT AND SHOE.—P. Kelly, 238 Kearny St., S. F. Patented June 22, 1886. No. 229,144. This invention relates to gaiters of the class in which elastic gores are used to allow the expansion necessary in putting on or taking off the gaiter. Heretofore, as is well known, it has been customary to place straight gores of elastic material in the leg of gaiters, such gores tapering from the top down to the point of termination at the upper edge of the counter or ramp. Such gores have ordinarily been placed on each side of the leg, about midway from front to rear, but have also been placed out of the central line to avoid the ankle-hone, which, when the elastic material is placed on it, is closely pressed, and also exposes said material more to wear. This invention aims to improve the appearance of the gaiter, and to avoid locating the elastic material over the region of the ankle-hone, and at the same time, by means of the curved shape of the gore, to adapt it to the form of the ankle-hone, while preserving the full effect of the elastic material, permitting the leg to expand without wrinkling.

MECHANISM FOR CONVERTING MOTION.—Thomas J. Bell, Grantville, Nye Co., Nevada. Patented June 22, 1886. No. 229,026. This device relates to certain improvements in steam-engines, and consists in providing the pitman or extension of the piston-rod with rack-bars or teeth, which alternately engage with and run from oppositely-placed toothed wheels on shafts provided with gears engaging with a common spur wheel on the driving shaft, so as to convert the reciprocating into a rotary motion without the intervention of cranks, and without having any dead points. It also relates to a certain means of arranging the teeth on the pitman, and combining them with slides carrying braces or lugs for shifting their bearings, and causing them to engage with the gear wheels on either desired side, so that the

motion of the driving shaft may be reversed at will, without the necessity of changing the valve motion.

BRECH-LOADING FIREARM.—Wm. R. Finch, Eureka, Cal. Patented June 22, 1886. No. 229,035. This invention relates to certain improvements in the construction of magazine firearms of that class in which a vertically-running breech-block is operated by a lever and serves as a carrier to transport the cartridge from the magazine to the rear open end of the barrel, into which it is forced by mechanism for the purpose. It consists in a novel construction and combination of a solid breech-block which is moved vertically in the frame at the rear of the barrel with a swinging arm, by which the cartridge is forced into the barrel, so that the breech-block is allowed to move up and close the breech. The whole is operated by a single lever beneath the gun, and the same action cocks the gun and locks the breech-block when closed, so that it cannot be opened.

GRAFTING TOOL.—Charles W. Hoyt, Petaluma, Sonoma Co., Cal. Patented June 22, 1886. No. 229,040. This device consists in the employment of a pair of pivoted handles, one of which is fitted to receive a curved wooden block or bed with an elastic surface, upon which the cutter acts, while the other operating arm moves the cutter which is pivoted to it. The upper end of the cutter is also pivoted to the end of a supplemental arm which extends back and unites with the handle upon the opposite side of the pivot, so as to produce a parallel motion of the cutter, which insures its making a straight clean cut whatever the thickness of the scion or stock to be operated upon.

The Fourth of July in San Francisco.

The arrangements for the celebration of the Fourth in this city are on a grand scale. The preparations being made by the different committees having the matter in charge, augur well for its success. The principal event of the day will of course be the procession, and this year there will be several new features added. During the march there will be a series of *tableau vivants* representing scenes in the country's history, such as the discovery of America, the landing of the Pilgrims, scenes of the Revolutionary wars, etc. Decorated arches will be constructed at the intersection of the main thoroughfares. The one at the corner of Market and Kearny is already assuming magnificent proportions, and when finished will no doubt be a credit to the designer. The Grand Army of the Republic and several other organizations have signified their intention to participate in the celebration. The Executive Committee has decided to have a public display of fire-works on the evening of the fifth, in some portion of the Western Addition. This is the first time in several years that there has been such a display. It is a fitting close to what, we have no doubt, will prove a day to be remembered by all. The Hon. John H. Dickinson is President of the Day, and Col. J. Henley Smith Grand Marshal. The literary exercises will take place at the Grand Opera House, and from the well-known ability of the different citizens who have been selected to carry out the programme a rare treat is promised. The selection of Dr. Shorb as orator is very fortunate, as he is one of San Francisco's best and most polished speakers.

People who desire to get away from the noise and bustle incident to the celebration in this city, will have an opportunity, as there are several excursions advertised to different points of interest. The San Francisco Yacht Club will celebrate the Fourth of July by a trip covering five days. As we go to press the fleet is preparing for a run to Vallejo, under command of Commodore Harrison. The morning of Friday will be spent at Mare Island. In the afternoon the boats will go up to Napa on the flood tide. A ball tendered to the club by the citizens of Napa, at the New Opera House, will occupy the evening. Saturday will be occupied by boat races, social visiting among the yachts and other pastimes, and a concert will be given in the evening. Sunday will be devoted to attendance at divine service, and on Monday morning at eight o'clock the fleet will be arranged in two columns, one under the command of the Commodore, and the other of the Vice-Commodore, and will be towed to Vallejo. There the tugs will drop the yachts, which will then proceed to a contest of speed to the Club House at Sausalito.

Thus it will be seen that the day will be fully honored in this city. This is as it should be, for the day upon which our forefathers sent out that noble document—the Declaration of Independence—to an oppressed people, should forever be green in the hearts of all Americans.

ANOTHER OIL FIRE.—Near the Acme refinery in Olean, N. Y., June 30th, lightning struck a 25,000-barrel oil tank, and set it burning furiously. A force of 100 men was immediately put to work digging trenches for the protection of the surrounding property; and oil and benzine were drawn off from the tanks in the vicinity. Fears were entertained that the fire would spread.

OUR EXPORTS AND IMPORTS.—For the year ending May 31st the exports of the United States exceeded the imports to the extent of more than \$162,000,000, which is a most gratifying exhibit. A few years of such prosperity will make the nation rich.

News in Brief.

A MACHINE for making pies has lately been patented.

ST. LOUIS finds from the census that her population is only 375,000.

It is thought this census will give four more Congressmen to Nebraska.

THE census just taken of Boston shows the population to be about 351,000.

THE annual conference of the Mormons will begin at Salt Lake city July 3d.

THE census of Chicago indicates that the population of that city is about 475,000.

THE work of repairing the old Mission of Carmelo, Monterey, is to be commenced.

RUSSIA is thinking of making the duty on iron so high as to be practically prohibitory.

ROME spends \$200,000 on its public schools, of which 10 years ago it had none at all.

LARGE quantities of wild strawberries are being brought into Olympia, W. T., by Indians.

THE North Palouse river of Washington Territory is capable of furnishing an unlimited water-power for manufacturing purposes.

THE German Bundesrath refused to entertain a petition for the reintroduction of silver currency.

ONCE again the British House of Lords has rejected the bill to legalize marriage with a deceased wife's sister.

ONE of the Indians lately killed in Grant county, New Mexico, had over \$400 in greenbacks on his body.

OF the 599,956,000 acres of land in our Territories, exclusive of Alaska, 489,533,000 have never been surveyed.

THE Duke of Bedford's remissions to his agricultural tenants during the last 18 months amount to over £100,000.

THE deficit in the Postoffice Department for the fiscal year of 1879 was \$3,407,916, which is less than any year since 1866.

THE Supreme Court of Nevada has decided that stock-owners are not responsible for the damage done on unfenced lands.

SHAD are being found in larger quantities near the mouth of the Columbia each year, and will no doubt become a staple article.

THE officials of the Agricultural Department say that the prospects are good this year for a large consumption of American wines.

AT Port Wine, Sissra county, June 2d, the snow was eight ft. deep on a level, and in the ravines and canyons it was much deeper.

AT Arivaca, Arizona, a rattlesnake was recently killed which measured 7½ ft. in length, 13 inches in circumference and had 29 rattles.

A LARGE buck was recently killed on Sonoma mountain. He weighed 700 lbs. when dressed, and his horns have seven points each.

RECENTLY the Russian floating battery *Kremlin* came in collision with a Danish steamer in the Gulf of Finland, and was seriously damaged.

AT this beginning of the present century there were 3,000,000 copies of the Bible in existence; since then 116,000,000 more have been printed.

IT is mentioned that the value of the diamonds exported from the Cape last year amounted to over three and a half millions sterling.

A MAN who firmly believes that a second flood will come next November to cover the whole face of the earth is building an ark at Helena, Texas.

THE accounts of last year's vintage in France are very bad. In the claret district no vintage in this century is remembered to have yielded so little.

A REVENUE posse, in attempting to capture moonshiners near Red Oak, Ga., were resisted. One moonshiner was killed and one mortally wounded.

A HORSE was driven upstairs into a drawing-room at Milton, England, but refused to come down again, and a part of the wall had to be taken out and the horse lowered by a steam crane.

THE steamer *City of New York*, of Alexander's Havana line, caught fire while lying at Brooklyn dock, June 24th, and burned to the water's edge.

AN inventor has patented a car that runs on skates instead of wheels, and is especially intended for elevated railroads. It runs on grooved rails.

A NEW society, "The Fraternity of the Holy Trinity," has been founded by the Spanish Jesuits for the express purpose of opposing the influence of Freemasonry.

A TERRIBLE ACCIDENT.—On Monday, June 28th, a terrible disaster occurred in the East river, by which over 50 passengers lost their lives. The steamboat *Seawanhaka*, which runs from New York city up the Sound to Glen Cove, took fire from an explosion in the engine room, and the center of the boat was soon aflame.

Charles Smith, the pilot, remained at his post until he was burned terribly, and ran the vessel on a sunken meadow adjoining Randall's Island. Passengers sprang overboard, and many were drowned; and others at the stern of the vessel were burned to death. The steamboat burned to the water's edge. No explanation has yet been given of the cause of the explosion in the engine-room which produced the fire. The complaint is general in New York city that the steamboat inspection laws are defective in the first place, and are recklessly violated in the second.

DURING the week ending June 6th, the shipments from the Utah mines amounted to \$104,609, including \$36,145 from the Ontario and \$8,450 from the Leeds.

Bullion Shipments.*

Since our last issue, we have noticed the following bullion shipments:

Paradise, June 25, \$4,189.55; Sierra Nevada, June 24, \$5,180.53; Northern Belle, June 23, \$7,265.07; Con. Virginia, June 26, \$60,056.03; Bodie, June 21, \$7,717; Christy, June 29, \$6,984; Northern Bells, June 29, \$8,019; at Salt Lake City, per Wells, Fargo & Co., June 23, Ontario, \$6,485.35; at Salt Lake City, per McCormick & Co., from Old Telegraph and Brooks, \$6,050; at Salt Lake City, per Union Pacific Express Co., Crimmon Mammoth, \$800, and Barbes & Walker, \$1,569.68; total, \$2,339.63; at Salt Lake City, June 24, per Wells, Fargo & Co., Ontario, \$5,985.11; at Salt Lake City, per Union Pacific Express Co., Christy, \$2,079.61; at Salt Lake City, June 25, per Wells, Fargo & Co., Ontario, \$4,206.10; at Salt Lake City, per Union Pacific Express Co., Barbes & Walker, \$1,534.23; at Salt Lake City, per McCormick & Co., Old Telegraph and Morgan, \$6,500; at Silver Reef, Col., for week ending June 26, per Wells, Fargo & Co., \$29,006.79; Northern Belle, for May, \$104,434; Alexander, for May, \$26,380.70.

*Desiring to make our list of Bullion Shipments as complete as possible, we will be thankful to receive from mining Superintendents and Secretaries notice of all bullion shipments from their respective mines.

NATIONAL BANKS.—The Controller of the Currency has just reported the number of national banks organized during the last fiscal year as 61, with a capital of \$7,352,070. This total number of banks which have gone into voluntary liquidation during the same period is 20, with a capital of \$2,601,000, included among which are three gold banks in California with a capital of \$700,000, which went into voluntary liquidation and organized as currency banks. No national banks failed from July 23, 1879, until June 9, 1880, since which time three banks failed, with a capital of \$700,000, all of which, it is believed, will pay their creditors in full.

OAKLAND HARBOR.—In reference to the long-pending controversy respecting the improvement of Oakland harbor, the Attorney-General decided, June 30th, that as the appropriation is available, the Government can, by virtue of its right to make improvements, use the bed or the streams, or their banks, at a proper distance above low-water mark, for any structure which it may deem appropriate.

MILLS AND METALLURGICAL WORKS.—We would call attention to the advertisement, in another column, of Messrs Taylor & Brunton. This firm is prepared to design, give estimates for and construct every description of mills and metallurgical works for the treatment of gold, silver or copper ores. Their principal office is at Leadville, Col. They have also a branch office at 68 Broadway, New York.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

HALL'S VEGETABLE SICILIAN HAIR RENEVER is a scientific combination of some of the most powerful restorative agents in the vegetable kingdom. It restores gray hair to its original color. It makes the scalp white and clean. It cures dandruff and humors, and falling out of the hair. It furnishes the nutritive principle by which the hair is nourished and supported. It makes the hair moist, soft and glossy, and is unsurpassed as a hair dressing. It is the most economical preparation ever offered to the public, as its effects remain a long time, making only an occasional application necessary. It is recommended and used by eminent medical men, and officially endorsed by the State Assayer of Massachusetts. The popularity of Hall's Hair Renever has increased with the test of many years, both in this country and in foreign lands, and it is now known and used in all the civilized countries of the world.

FOR SALE BY ALL DEALERS.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Fishbe, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

Chester Jackson's Best Sweet Navy Tobacco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Gover Mining and Milling Company.

Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

NOTICE.—There are delinquent upon the following described stock, an account of assessment (No. 42), levied on the Fifth day of May, 1880, the several amounts set opposite the names of the respective shareholders, as follows:

Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

HYDRAULIC GRAVEL ELEVATORS,

For working flat
gravel mines that
have no dump.

Sluices gravel and
water up hill on an
angle of 45°, and
will run any kind of
gravel that will run
in a flume. Handles
rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, Its Formation and History." This
very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing
sections, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & Co., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The pan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over all other Steel Castings. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists free. Address

Gold Miners

WORKING PLACER, GRAVEL AND QUARTZ MINES,

SAVE YOUR GOLD!

- BY USING -

SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save a very much larger percentage of gold than any other method. Thousands of orders filled and the demand constantly increasing. Having very extensive facilities for the manufacture of these Plates, will fill orders for California, Colorado, Montana, Dakota, Oregon, Idaho, Utah and adjoining States at prices which defy competition. Metal Goods of every description, including Musical Instruments used by Brass Bands, plated.

San Francisco Gold, Silver and Nickel Plating Works,

633 and 655 Mission St., bet. New Montgomery and Third, San Francisco.

Attorney-at-Law,

Notary Public and Commissioner of Deeds

209 Sansons St. Bet. California and Pine, S. F.

Connection in every town in the State for collection of debts.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

PATENT LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning
and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS
Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. 12 Triple Force Caps and all Grades of Fuse.

BANDMANN, NIELSEN & CO.,
SAN FRANCISCO, CAL.

VULCAN BLASTING POWDER.

The Strongest, Safest, Most Uniform and Reliable "HIGH EXPLOSIVE" Manufactured on the Coast.

MINERS TESTIFY THAT IT IS FREE FROM OBJECTIONABLE FUMES.

We call the attention of all desiring such a Powder to our various grades, which we are prepared to sell at LOWEST RATES.

No. 1.—Equalling Liquid Nitro-Glycerine in Strength. We recommend this Grade in extremely hard rock, boulders, iron, etc.

No. 2.—Will do the work thoroughly in all but the hardest kinds of rock.

No. 3.—For bench work, pipe-clay, soft and shelly rock, outside work and quarrying.

Single and Triple Force Caps, Fuse of all Grades, Vulcan Powder Thawing Boxes, Batteries and Exploders, For Sale at the Lowest Rates.

Number 2.

Rich Gold-Bearing Deposit.

The great activity which has prevailed lately in the mining regions of California is not only encouraging but has a substantial practical value. Many a mining camp which has been long abandoned has been aroused into active life by the discoveries made in a distant or an adjoining section; and this again has reacted as the incentive for a renewal of hope and exertion in other mining properties which had apparently exhausted the means and patience and even the hope of the owners. This general renewal of work has already given a new and more enduring tone to the gold-bearing ledges which seam the mountains of California like a network, no less than do the auriferous gravel deposits which lie imbedded in hill and plain. The old activity is bearing some of the old fruit, and there seems to be an assurance that the product of gold in California will largely increase for years. The new and favorable condition of the mining industry has imparted tone to the general business. It has arrested the attention of hitherto indifferent capitalists who are now reported to be buying and inquiring for tangible gold properties. This fact should impel the owners of quartz ledges and gravel deposits to develop them to a point where their value might be ascertained to a reasonable certainty, and where the investor's risk would be reduced to a minimum.

We have been led to make these remarks after reading this account in the Nevada Transcript of the extraordinary discoveries recently made at Snow Point, in Nevada county. It appears that the owners of the property have been earnestly at work in its development for several years. They were both energetic and patient, and they are now likely to reap their well-earned reward. We are not informed of the area of this gravel claim, but we believe it is extensive. There is an occurrence at the mine which is full of interest; and that is the large percentage of black sand which is interspersed through the gravel, and which is reported to carry largely of fine gold. An experiment made with two pounds of this sand, after grinding and amalgamation, gave a yield of \$2.75 in gold. No gold was perceived by the naked eye or with the aid of a glass. The proportion of the black sand is estimated at one ton to the hundred of gravel. Coarse gold prevails in the gravel, and nuggets valued at \$200 were found; and it is said to be an ordinary occurrence for the miners to pick up pieces weighing from 1 to 12 ounces. It is reported that the gravel pays for a depth of 25 ft. above the bedrock. The mine is only partially opened, but the owners assert that it has yielded more gold for the area of ground drifted than any other gravel claim in the State has for many a year. The amount of this rich find is cheering, and it ought to fortify miners with a larger hope for the coming of their lucky strike.

GOOD NEWS.—A dispatch from Dublin, July 6th, conveys the cheering intelligence that the weather all over Ireland, up to the present time, has been most favorable for the crops. It is expected that the crop of potatoes will be enormous; indeed, it gives full promise of exceeding any crop of potatoes seen in Ireland since a period anterior to the blighting famine of 1847. The crops of cereals and of roots generally are also said to be luxuriant. Even the meadows, which alone were backward, have been quickened by generous rains, and give promise of a fine yield.

THE CHANNEL TUNNEL.—It is announced that the preliminary works of the tunnel which is to connect England and France have had the most satisfactory results. The managers have sunk their shaft to the stratum in which they propose to bore the tunnel, and are now about to sink another shaft and lower all the machinery for the bore. It is estimated that in about 18 months they will have bored at least 2½ miles under the channel, and that the work will be completed in four years.

Waugaman's Dry Gold Washer.

This is a late invention which promises to fill a want long felt in certain localities where water cannot be obtained without too great an expense, for purposes of washing or concentration.

This gravel or other material from which it is desirable to separate the gold or other heavy portion, is, if necessary, first screened through a coarse screen, throwing out any pieces larger than about half an inch in diameter. It is then thrown into a hopper which discharges on to a shaking screen having a mesh adapted to the character of the material.

This screen has a slight incline either way from a central apex directly under the hopper, and is provided with a rifle at either end to retain any gold too coarse to pass through it. Its object is to further eliminate gravel too coarse for the succeeding treatment, and to distribute the material properly on the upper edge of an inclined apron. This apron is constructed of coarse wire cloth covered with common sheeting, and set in a shallow frame. The frame is traversed with narrow wooden strips which serve as rifles and also to keep the sheeting in position on the wire cloth. This frame or apron rests on cleats and is keyed into the square body of the machine, and though it is readily removed for cleaning, it is kept stationary while the machine is in operation. Beneath the apron is an oscillating hollow so arranged that its flaps can escape only through the porous material of this apron (or through waste valves arranged to regulate the draft and adapt it to different classes of material.)

When ready for operation the hopper valve, which regulates the feed, is opened far enough to pass a proper supply, and the gearing set in motion by hand or other power. All the material which passes through the shaking or grizzly screen is evenly distributed on the upper edge of the apron above the first wooden strip or rifle. The sudden puffs of air from the oscillating hollow, coming through the wire and cotton cloth of the apron from beneath, lift or throw the sand and fine gravel up and permit it to settle back during their intermission. As the apron is inclined, the lighter parts of the stuff rapidly work down to the discharge, while the heavier is retained mostly in the upper rifle, the gusts of wind not being strong enough to throw them over it.

These machines weigh about 150 pounds, can be taken to pieces for packing and will no doubt be found of great value in remote "dry diggings," as they are especially adapted to gravel washing. The above description carefully read in connection with the illustration herewith presented, will give the reader a very good idea of the construction and mode of working the machine. These machines are manufactured and sold under the firm name of C. J. & E. T. Barber, and may be seen in practical operation, daily, at No. 2 Summer street, in this city.

CURIOSITIES OF THE CENSUS.—The census reveals many curious things, which, if collected in a volume, would make entertaining and valuable reading. For example: In Arizona, on a stream called Moencopy, which empties into the Little Colorado northwest from the San Francisco mountains, the census taker found a flourishing settlement of Mormons engaged in farming and stock-raising: they have a woolen mill run by water-power. North of the Moencopy there was found a Navajo Indian who is rich in patriarchal goods—flocks and herds. He has over 15,000 sheep and goats, and more than 500 head of fine horses.

Railroad Building in Mexico.

A writer of notes recently expressed the opinion that the railroad system was destined to be the chief agent in regenerating the republic of Mexico. It would appear that the zeal which the more intelligent and substantial people of that country are manifesting on the subject of railroads, is likely to soon put the soundness of this judgment to the test of experiment. The U. S. Minister to Mexico has just sent a communication to Washington, conveying the intelligence that various projects for the construction of railroads had seriously engaged the attention of Congress and the people, and that this condition of things would be likely to produce a corresponding interest in the United States, whose capitalists would probably be called upon to supply the means to carry out those enterprises. The Mexican people were, until a recent period, decidedly opposed to railroad projects, but it is represented that they now very earnestly favor them. The construction of such roads as are most necessary and feasible will require the expenditure of millions of dollars.

The valuable concession made to Camacho and others in 1874, to construct a broad-gauge railroad and telegraph line from the city of Mexico to Leon, in Guanajuato, was declared forfeited in December, 1876, by the supreme authority of that State. This contract, with enlarged concessions, was transferred by the President to Symon & Co., April 3d, 1880. Previously, however, in November, 1877, W. J. Palmer & Co. had entered into an agreement with the Minister of Public Works to build a network of narrow-gauge roads from the city of Mexico to the Pacific on the one side, and to the frontier of the United States on the other. Consequently, as the subject demanded the approval of the Mexican Congress, its session, which has just closed, has been agitated by the respective claims of these two companies. As a compromise, the question of which shall enjoy the right has been referred by Congress to the decision of the President of the republic. Either of the companies to which the contract may be awarded, would be entitled to a subsidy from the Mexican government, but it goes without saying that the payment of subsidies would be onerous, difficult, and, perhaps, impracticable for many years. The railroad in Mexico means the establishment of law and order, and full protection to property, the promotion of industry and trade, easy and rapid communication and the gradual conversion of isolated, remote and discordant States into homogeneous and friendly neighbors. The steady operation of a system of railroads through the interior and to the frontiers, would doubtless effect such a radical and beneficent change in the condition of Mexico, as to gradually render the subsidies of practical value. But in our judgment the railroad must come first.

MINING MACHINERY FOR MEXICO.—We learn that Messrs. Prescott, Scott & Co., of the Union Iron Works, are manufacturing a 20-stamp quartz mill for a mining company near Carhoca, Mexico. When completed, the machinery will be shipped to Port Libertad, in the Gulf of California, some 27 miles from the point where the mill is to be erected. The estimated cost of the mill, in perfect working condition, is \$60,000.

HONORING WOMAN.—The first woman who has had entire charge of the female department of Pennsylvania's new hospital for the insane, Dr. Alice Bennett, wore a cap and gown at the recent commencement of the University of Pennsylvania, held in the city of Philadelphia, and received the degree of Doctor of Philosophy.

California Copper.

The San Francisco copper mining company have recently received and have now at Lowell's warehouse, on Davis street, 1,072 bars of copper from their mines and reduction works, at Spencer-ville, Nevada county. The copper is of commercial fineness, is put up in Lake Superior shape, about 18 lbs. to the bar. This company has the right to claim the first production of commercial copper on the Pacific coast direct from the ore.

This mine and works of the company are quite extensive, they have now 12,000 tons of ore in process of calcination, with a capacity for producing from 40 to 50 tons of copper per month. The gross product of each ton of ore worked is about \$12.50, with a net profit of about \$8.25. The plant of the company was fully described in our issue of Feb 15, 1879. It is on quite an extensive scale, and after the most approved of modern appliances. In view of the efforts of this company to produce copper in quantity, and the reasonable supposition that the yield of the mine will realize an annual increase for years to come, and probably encourage other mining enterprises in other portions of the State, it is to be hoped that some of our enterprising capitalists will find it a profitable enterprise to put up rolling and other machinery in this city for working up this product into sheet copper, wire, bolts, rivets, etc. There is a large margin for profit between the price of ingot and manufactured copper. Without this advantage the company will have to seek a market abroad for their ingots, which will be returned to us again as manufactured copper, at rates greatly in advance of what it could be manufactured for in this city.

The International Exhibition of 1883.

The act of Congress incorporating an International Commission for holding a World's Fair at New York in 1883, calls for the appointment of two commissioners from each State and one from each Territory—these to be joined to the commissioners named in the act—the entire number to constitute a commission for initiating and conducting the fair. Pursuant to this act the necessary appointments have already been made, and the commission will soon commence active work. The appointments for this coast, so far as we have learned, are as follows:

CALIFORNIA.—Henry George and Warren B. Ewer, Commissioners; with Geo. Francis Dawson and Walter Hart as alternates.

NEVADA.—John W. Mackay and M. P. T. Finch, Commissioners; with Richard S. Rising and Allen A. Carter as alternates.

NEW MEXICO.—H. M. Atkinson, Commissioner; with S. H. Newman as alternate.

The first duty of the commission will be to effect a temporary organization and provide for the opening of books of subscription to the capital stock. They will then adjourn, and the subscription books will remain open for 60 days, at the expiration of which time there will be a meeting of the commissioner and stockholders, who will elect a Finance Committee of 25, to superintend that special department. The entire commission will then effect a permanent organization, elect officers, adopt by-laws, appoint committees, etc., when strenuous efforts will be at once commenced to complete the arrangements for the exhibition, and make the same a grand success.

SUFFERINGS OF A RAILROAD CORPS.—Recently from Galveston, Texas, there came a dispatch from Fort Stockton, which says that Major Lawrence and corps, attached to the Texas & Pacific R. R., after a number of days of extreme privation and suffering, arrived at the Pecos river. The party had abandoned both stock and wagons at different intervals along a course of about 40 miles. The members of the party who arrived first at the river went in search of the missing men, many of whom were found crazy from the effects of prolonged thirst, and were entirely stripped of their clothing. They were encountered within 100 yards of the Pecos river, drinking the blood of animals they had killed. The brave conduct of the most experienced members of the corps saved a large number of the men from perishing.

WAUGAMAN'S DRY GOLD WASHER

MECHANICAL PROGRESS.

The Sensitiveness and Isochronism in Governors.

An interesting paper was recently read before the English Society of Mechanical Engineers, on the above subject, from which we extract the following paragraph:

As the attainment of a regular rate of speed is the only object of a governor, it is an interesting inquiry how far this result is achieved by the sensitive and isochronous governors, now frequently applied to steam engines. The irregular manner in which power is communicated from a piston to a crank causes periodical variations in speed, which vary greatly in their degree between such classes of steam engines as the common agricultural type and the high-class mill engine. Whenever there is great sensitiveness in a governor, it is often found that inherent irregularities in speed tend to such an extent that this governor becomes uncertain, runs from one extreme of its range to another, and produces hopeless confusion in the speed of the engine it was intended to regulate—giving, in fact, a worse result than would be produced by a governor of the common type. This evil has been remedied by retarding the movement of sensitive governors, causing their movement to force fluids through small orifices, an unreliable method now superseded by a method invented by the author, whereby the balls overcome the inertia of a mass of metal as they move in or out, a plan applicable to the usual type of governors, and also to those which are direct-acting, fixed upon an engine shaft and altering the stroke of an expansion eccentric. Thus, such governors may be made to effect a more uniform regulation than has hitherto been attainable, and their extreme simplicity remains without attendant disadvantages. An illustration of the relay system was given, where the governor moves a valve admitting hydraulic pressure under a plunger to raise or lower the sluice of a turbine, and so regulate its rate of motion. It was finally shown that governor and engine should correspond in their relations so as to work harmoniously together; and that perfect regularity is unattainable, and can only be approached by providing sufficient inertia in the moving parts to diminish the effect of irregularities in power or resistance until the governor can operate; and that a high rate of revolution attains this condition with the greatest economy and success; and that although the governor may advantageously approach isochronism, its sensitiveness must not be excessive.

NEW STEAM BOILER.—Below is a description of an improved compound steam boiler patented by Mr. Robert R. Hind, of Kohla, Hawaii, Hawaiian Islands. It is designed especially for utilizing cane trash or bagasse, or any other light fuel. These boilers have been largely introduced in the Hawaiian Islands, and have earned a reputation for being very economical steam generators and exceedingly well adapted to any fuel supplying a long flame. The boiler is composed of a single flue or Cornish boiler, and a multitubular boiler, placed end to end, leaving a space between them. These boilers are connected together at the top by a steam drum, and at the bottom by circulating pipes. The Cornish boiler is set directly over the furnace, with the end next to the tubular boiler over the grate, the firing being done at the side. The products of combustion and flame pass backward under this boiler and forward through the single flue, across the space between the two boilers, and through the tubes of the tubular boiler to the chimney. A portion of the heated gas and flame is made to circulate under the latter boiler before passing to the chimney. This boiler is highly spoken of by owners of sugar plantations in the Hawaiian Islands, and it might be profitably employed in saw mills, planing mills, and in manufactories relying on waste and on light fuel for generating steam.

MOTIVE POWERS OF THE FUTURE.—A suggestive paper was recently read before the Liverpool Engineering Society on "The Utilization of the Tides," by Mr. Oates, of Bradford. Mr. Oates was of opinion that although the coal supply of England would last for a long time to come, yet that ultimately the power of the tides would outrival all other sources of mechanical power. After pointing out that the ways of utilizing the tides were innumerable, and describing the construction of the tidal dam with suitable converters of the power, such as turbines in openings of the dam, working air-compressing or magneto-electric machines, he stated that the necessity for large conservators for storing the power between the tides would be the greatest difficulty in utilizing their power. A brief description of how this could be done and the power rendered constant was given. The means of conveying the power to a distance was then considered, air and water pressure and electricity being suggested. With regard to the latter, Mr. Oates believed that the "age of steam" had reached its zenith, and that the "age of electricity" had dawned; but should there be difficulty in conveying the power to a distance, he suggested that manufacturing towns might be built adjacent to suitable sites for utilizing the tides.

The New Steel Processes in the United States.

At the recent meeting of the British Iron and Steel Institute, Mr. Holley being requested by the president to give some account of the steel manufacture in the United States, stated that several works there were preparing to use the basic process; but they had not employed it at all yet or made experiments with it. The opinion of the Bessemer steel makers in the United States was very favorable to the new process. In many parts of the States phosphoric irons were very cheap, and they were going to put this process in useful operation in those parts. The chemical process appeared to be certain, and the American manufacturers thought that there were no great difficulties to be overcome. Perhaps it was proper he should mention that two other processes were, in America, making steel from highly phosphoric iron. They had found a considerable improvement in the open-hearth process by using the Pernot furnace. Several of these were working, but had not been at work long. They, however, gave promise of success; and they believed that in a single Pernot furnace they would be able to produce nearly 100 tons of ingots in 24 hours. It thus appeared that the open hearth would have a large output due to this improved French invention. The Siemens direct process was not much in use; but it was in regular use for manufacturing a very fine steel for boiler plates, which is very extensively used. Nearly every fire-box in America is made of steel. The blooms from which they produced this fine steel is like that of the open hearth. Another process attracting attention in America was the Krupp process, which took out 65% of the phosphorus from pig iron by puddling in a revolving furnace. It is not in use yet, but this result at the Krupp works shows what the American result would be. In regard to the basic process the Americans would not be discouraged about it even if at this outset it did not pay, because they were satisfied that the difficulties were of a mechanical nature and could be overcome.

TO KEEP WAGON TIRES ON THE WHEEL.—A practical mechanic suggests a method of so putting tires on wagons that they will not get loose and require resetting. He says he ironed a wagon some years ago for his own use, and, before putting on the tires, he filled the felloes with linseed oil, and the tires have worn out and were never loose. This method is as follows: He used a long cast-iron heater made for the purpose; the oil is brought to a boiling heat, the wheel is placed on a stick, so as to hang in the oil, each felloe an hour. The timber should be dry, as green timber will not take oil. Care should be taken that the oil is not made hotter than a boiling heat, or the timber will be burned. Timber filled with oil is not susceptible of injury by water, and is rendered much more durable by this process.

WORKING STEEL FOR TOOLS.—In working steel for tools, great care should be taken to hammer all sides alike, for if one side is hammered more than another it will cause it to spring in hardening. Again, steel, when being hammered, should be heated as hot as it will stand, until finishing, and should then be hammered until almost black hot, for the reason that it sets the grain finer, and gives the tool a better edge. The reason for heating the steel so hot while hammering is simply because it makes the steel tougher when hardened, and softer when annealed, while if it were worked at a low red heat, the continued percussive shocks of the hammer would so harden it as to make it almost impossible to anneal it, and at the same time render it brittle when hardened.

EFFECT OF AGE ON THE QUALITY OF IRON.—Prof. Bauschinger, in 1878, tested iron taken from a chain bridge built in 1829, and found that 50 years of use had not perceptibly altered its quality—either its strength or its elasticity—as reported at the time of its erection. He also examined metal from another bridge built in 1852, and found that the average quality remained as given by Von Pauli at the time of its erection. Prof. Thurston, testing pieces of the wire cable of the Fairmount suspension bridge, recently taken down at Philadelphia, after about 40 years' use, found the iron to have a tenacity and elasticity and a ductility fully equal to the best wire of same size found in the market to-day. He therefore concludes that iron subjected to strains such as are met with in properly designed bridges does not deteriorate with age.

BESSEMER steel is now produced of so good a quality, that competent judges assert that ere long it will supersede crucible steel, even in the cutlery manufactories of Sheffield. Already, as it appears, they are making the cheaper grades of cutlery, edge tools, etc., from this product, some 50% to 75% in value of goods produced being accredited to the use of the best quality of Bessemer.

MINERAL-TANNED LEATHER is impervious to water, and is said to be much more durable than leather prepared in the ordinary manner. Tests have been made, which show that helts of mineral-tanned leather are not only 30% cheaper, but are stronger than common belts. The mineral process of tanning is reported to have been introduced into eight tanneries in Germany.

SCIENTIFIC PROGRESS.

An Important Discovery.

A discovery in chemistry has just been published which bids fair to influence agriculture in a manner that may be well described as revolutionary. It must soon compel the attention of farmers and manufacturers of artificial manures everywhere. The essential part which ammonia plays in vegetation need not here be dwelt upon, and no one will question the desirability of securing it cheaply and in quantity. The importance of the recent feat of Messrs. Rickman & Thompson, of England, disclosing a plan by which ammonium sulphate can be made and sold with profit at two cents a pound, will not, therefore, be liable to be over-estimated. The following account of the process is taken from the *Chemical News*.

Within the last 20 years the manufacture of ammonia synthetically has been several times attempted, and though in every attempt it is probable that ammonia has been made, it has never been produced on a commercial scale. In all these attempts the process has been to combine the nitrogen and hydrogen directly at a low temperature, and receive the ammonia in solution in water, or by substitution, first forming a cyanide at a higher heat, and then indirectly producing ammonia by the decomposition of the cyanide, the result in both cases being ammonia in solution with water. Rickman & Thompson's procedure is altogether different, they produce ammonium chloride direct, either in dry powder or in solution, and this by the simplest and most inexpensive means. Instead of employing retorts, as in all other places, they merely use a closed brick furnace, the ash-pan of which regulates the supply of air, and they cause the vapor of water to be produced by this waste heat of the furnace itself. With the exception of about a bushel of coke for starting the furnace, the deoxidizing material and only fuel used is coal-dust. The great difficulty in making ammonia from the nascent hydrogen of water and the nitrogen of the air is the restricted limits of temperature between generation and decomposition, it being necessary that carbon, however used, should be at a full red heat to decompose the vapor of water, and at a bright-red heat to decompose ammonia. Now, ammonium chloride under the same conditions is simply volatilized and not decomposed. As chloride of sodium or of calcium is decomposed at a full red heat in presence of nascent ammonia, therefore one of these chlorides is mixed with the coal that ammonium chloride may be formed; so that if by chance the heat should be raised to a bright red, no loss will be sustained—the ammonium chloride is simply volatilized. By these means a greater range of working temperature is obtained. At the present time, with the consumption of from 20 to 25 lbs. of coal-dust and salt mixed, from two or three lbs. of ammonium chloride is formed.

PROGRESS IN UTILIZATION OF SOLAR HEAT.—Since May last year, M. Mouchot has been carrying on experiments near Algiers with his solar receivers. The smaller mirrors (0.80 m.) diameter have been used successfully for various operations in glass, not requiring more than 400° to 500°. Among these are the fusion and calcination of alum, preparation of benzoic acid, purification of linseed oil, concentration of syrups, sublimation of sulphur, distillation of sulphuric acid, and carbonization of wood in closed vessels. The large solar receiver (with mirror of 3.80 m.) has been improved by addition of a sufficient vapor chamber and of an interior arrangement which keeps the liquid to be vaporized constantly in contact with the whole surface of heating. This apparatus on November 18th, last year, raised 35 liters of cold water to the boiling point in 80 minutes, and an hour and a half later showed a pressure of eight atmospheres. On December 24th M. Mouchot with it distilled directly 25 liters of wine in 80 minutes, producing four liters of brandy. Steam distillation was also successfully done, but perhaps the most interesting results are those relating to mechanical utilization of solar heat. Since March the receiver has been working a horizontal engine (without expansion or condensation) at a rate of 120 revolutions a minute, under a constant pressure of 3.5 atmospheres. The disposable work has been utilized in driving a pump which yields six liters a minute at 3.50 m. or 1,200 liters an hour at 1 m., and in throwing a water-jet 12 m. This result, which M. Mouchot says could be easily improved, is obtained in a constant manner from 8 A. M. to 4 P. M., neither strong winds nor passing clouds sensibly affecting it.

SULPHURIC ACID AS A DISINFECTANT.—The *British Medical Journal* reports the publication, by Prof. Gamgee, of a new and convenient mode of using sulphurous acid, the disinfecting qualities of which are universally known. Cold alcohol, the professor asserts, will dissolve 300 times its own volume of the gas; and a fluid possessing such powers of concentration cannot but be as efficient as it is portable and convenient. A few drops of the sulphureted alcohol in the bottom of a trunk will disinfect any clothing that may be put into it; and fungous germs, such as must in casks, etc., may be destroyed by the use of a very small quantity.

Atmospheric Polarization.

The philosophers who, from the time of Arago, have busied themselves with atmospheric polarization, have concluded that the plane of polarization of the light sent from any point of the sky passed through the sun, or was perpendicular to a plane passing through that luminary. M. Becquerel was led to think that this coincidence did not generally exist, so that he undertook the problem of determining exactly the relative positions of the sun and the plane of polarization. After accumulating the results of two years' observations he has come to the conclusion that if we call a plane passing through any point of the sky the eye of the observer, and the center of the sun the *sun's plane*, then there is a variable angle between that plane and the plane of polarization of the light coming from the particular point in the sky looked at, such that the plane of polarization is always below the sun, that is, between it and the horizon. If the point looked at be north or south, and near the horizon, the angle is small in the early morning, reaches a maximum about 9 or 10 A. M., becomes naught at noon, reaches another maximum at 2 or 3 P. M., and becomes naught again at sunset. Toward east or west no exact coincidence of the planes is observed, but there is a minimum about noon. In the morning and evening the angle between the sun's plane and the plane of polarization is tolerably large, as much as 6°; but near the time of coincidence there are perturbations which have prevented M. Becquerel following the movements of the plane of polarization near sunrise and sunset.

All the phenomena observed lead to the conclusion that the plane of polarization is twisted in the positive direction as seen by a person with his head toward the north and his feet toward the south, and that in the region perpendicular to the dipping needle the plane of polarization suffers practically no twist. The author is, therefore, led to the conclusion that this rotation of the plane is due to terrestrial magnetism. Certain investigations, not yet concluded, have enabled him to calculate *a priori* the possible amount of rotation producible by the earth's magnetism when the thickness of air through which the light comes is known.

This thickness has of course not been accurately determined; but by making certain hypotheses he has arrived at the result that the probable theoretical amount of rotation of the plane of polarization due to terrestrial magnetism is of the same order as the observed value. At the same time, the theoretical value is too small to enable him to conclude that terrestrial magnetism is the sole cause of the observed rotation.—H. Becquerel, in *Jour. de Physique*.

Dr. Siemens' Newest Electrical Results.

A paper was read, June 7th, in London, before a crowded meeting of the Society of Telegraph Engineers, by Dr. Siemens upon "Recent Applications of the Dynamo-Electric Current to Metallurgy, Horticulture and the Transmission of Power." In this paper Dr. Siemens said that he was prepared to corroborate a statement which he had made on a previous occasion; affirming the applicability of the dynamo-electric current to hitherto unaccomplished purposes. Among these purposes was the transmission of power, and the accomplishment of large chemical results, such as the decomposition of metallic salts. The electric arc was capable of producing intense heat with a moderate expenditure of energy, and of effecting the fusion of even platinum or steel. Amidst loud applause, Dr. Siemens personally illustrated this by the experiment of melting two quantities of steel in a plumbago crucible, the first being fused within a quarter of an hour, and the second within the short space of eight minutes. Proceeding to describe the effect of the electric arc on horticulture, Dr. Siemens related the result of some experiments he had made in this direction. They went to prove that the electric light was efficacious in ripening fruit, and if this should be confirmed the horticulturist would become independent of solar light in producing a high quality of fruit at all seasons of the year. With regard to the application of the dynamo-electric current to mechanical propulsion, Dr. Siemens gave details of a practical trial which had been made in Berlin of a toy railway on this system, and the success attending this had given rise to the idea of useful applications of the motor on a larger scale.

FORCE EXCITING ELECTRICITY.—Every heat phenomenon, emission as well as absorption, occasions under favorable circumstances an electric current. The current produced by the emission of heat has the opposite direction from that produced by absorption. If only one metal in a galvanic element is active, the electric force is proportional to the algebraic sum of the heat developed by the bodies acting upon each other within the element. If both metals are active the electric force is proportional to the difference of the algebraic heat sums on the one and the other side. The power of polarization in exciting electricity depends neither on the nature of the gas nor of the metal, but mainly on the chemical action springing from electrolysis. The power of two metals in one acid to produce electricity stands in a simple proportion to the heat which the metals in question evolve when they unite with the acid to form salts.—*Rad. Jugosl. Ak.*

The Mining Share Market.

This has been a short and a dull week in the mining share market. After the long adjournment, the Board opened on Wednesday, but transacted very little business. The declaration of a dividend on Con. Virginia shares created a little stir, and caused some demand for the stock, but in other respects the Comstock shares have been quiet. In outside stocks there has been inquiry and sale for Northern Belle; and among the Bodies, Addenda showed some activity. Beyond these meager transactions the share market remained as it has been for a period beyond which the memory of the veteran dealer runneth not to the contrary.

Meanwhile operations of great magnitude continue and grow upon the Comstock. The *Enterprise* remarks that the drift from the bottom of winze No. 1, on the 2500 level of Union Con., which is to connect with the Sierra Nevada, and which can be done with a little work, will show very close to the heel of the ore-body, and may possibly cut into it. The low-grade quartz through which the drift on the 2500 level, between the two winzes, is progressing, is doubtless the east casing of the ore-vein. It is probable that a west crosscut, started at almost any point in this quartz, would soon run into ore.

The reports from the mining regions of this State continue to be satisfactory. In Nevada, outside of Storey county, in Utah, Arizona, Montana and Idaho, reports of activity, discovery and production are rife, and the general mining situation may be pronounced encouraging.

about 1,500 ft in length, giving several hundred ft of lift or backing to one of the best mines of that section.

EL CARMENA.—The extent of the work done on this mine, up to the present time, is a shaft some 300 ft deep and a tunnel some 100 ft in length, which has been done by parties of limited means, who were not able to erect a suitable mill and provide machinery requisite to successfully crush the ore. We have been assured, by good authority, that not a pound of ore has been taken out of the mine worth less than \$100, and from that to \$500 per ton. The last 53 tons taken from a little below the 300 level yielded \$1,700.

NEVADA.

SPARKO MINE.—*Herald*, July 1: The 4-stamp mill recently erected at the Sparko mine, commenced running in full blast last Monday. The mill is situated on Deer creek, a few hundred yards above the Providence mine. A tunnel has been run in about 300 ft on the ledge, which is of a fair size and contains rich sulphurets.

MOUNT AUBURN.—*Transcript*, July 2: Good ore was struck in the north drift of the bottom level at the Mt. Auburn mine, Tuesday morning. The ledge is estimated to be about 2 ft thick. The management have displayed much faith and nerve in their long-continued search for the lead which they have not encountered before in the lower workings of the claim.

ECREKA LAKE AND YUBA CANAL CO.—This company is making preparations to open their lead at North Columbia, where the ledge is about 10 ft thick, and if they can get the McKilloch hoisting works, they are being removed to the site where it is proposed to sink, and the shaft will be sunk as rapidly as possible. It is believed that this gravel will be found within 150 ft of the surface.

RICH WATZ DUMP.—D. Leach has met with excellent results in his experiment of sorting over the mammoth waste dump of the Banner quartz mine, on which work was suspended several years ago. Several half tons of ore were picked out from the debris and just crushed and assayed, yielding \$100 per ton in free gold and \$20 in sulphurets worth at the rate of about \$150 per ton. Mr. Leach proposes to work over all the ore in the dump, there being many hundred tons of it.

NOTES.—The Yuba water and mining company continue running a full head of water to Chalk Bluff and Blue Tent, and will be engaged to do so for several weeks to come. Jacobs & Sargent, Turner, Noyes, Sterling and all other mine owners down this way have been shut off, and will have to remain idle till the rainy season sets in.

CHLORINATION WORKS.—The erection of the new chlorination works at the Merrifield mine in this district has commenced, and will contain the most approved modern appliances for treating the large quantities of auriferous sulphurets produced by the mine.

SPARKO MINE.—*Foothill Tidings*, July 3: The strike made last week in the Wand & Blackwell claim at Snow Point in the upper part of this county is said by a mining expert who visited it this week to be most important gravel discovery made on this coast within 25 years. Numerous large nuggets continue to be found, and Supt. Blackwell is increasing the force, expecting soon to have 50 men at work.

YUBA M. M. CO.—This company has now got fairly at work. The ledge in the lower main tunnel is some smaller and of good quality. In the raise the ledge is of good size and quality—some of it rich. The mill is at work and everything running smoothly. The company have decided to build a new water wheel and flume and put in an air compressor and drills, intending to push the development of the mine as fast as possible.

SPARKO MINE.—This mine is on the other side of the river from the town of Washington. The owners are pushing the work on the mill, the frame of which is now raised. Report has it that a very rich boulder was found in the croppings last week, from which several thousand dollars was taken.

ITEMS.—The Last Chance mine at Sawmill Flat will soon be started, when a good sized crushing will be taken out at the mill, and if the return is satisfactory the construction of a mill will be commenced. Osborn & Co., owning the adjoining ground to the Last Chance, have a good showing. Arrangements are about being made with men of means to fully open up this property.

HYDRAULIC CLEAN-UP.—North San Juan Times, July 3: The Lone Ridge M. Co. made a clean-up a few days ago which was very satisfactory to the owners. They refuse to have the mine reworked, but they do say it was better than they anticipated.

PLACER.

FRANKLIN M. CO.—Dutch Flat *Forum*, July 3: This company is progressing steadily with the prospecting drift, which is now in 10 ft from the bottom of the shaft. No bedrock has been discovered as yet.

ITEM.—The supply of water in the South Yuba canal company's ditch is diminishing, so that they have been compelled to shut off the supply of several of the gravel mining companies in the vicinity of Quaker Hill.

MINING NOTES.—*Herald*, June 20: The mines are paying better than ever, both at Gold Run and Dutch Flat, and the times, in consequence, are booming. The Cedar claim at this place has commenced working for the first time this season, and expects to get in two or three runs. R. S. Alderson and others have located and are now engaged in sinking a shaft on a quartz lode at Secret Town.

MONO.

LAKE DISTRICT.—Mammoth City *Herald*, June 30: The ore which is now being run down to the mill is pronounced by all who are familiar with the products of the Lake district mine to be of higher grade than any heretofore worked from the Mammoth mine, and it is only fair to say that a result which will awaken a genuine interest in our mountain district and spur the owners of other properties to renewed efforts.

MERRIMAC.—This property lies between the True Blue and Monto Cristo, and there is quite a stir among the mining men in the neighborhood in consequence of the relation of the vein to those lodes. We have not seen the specimens, but they are said to compare favorably with the best samples taken from the Hardy winze of the Mammoth mine.

LAST CHANCE.—In this promising claim, situated on the southern end of Mineral hill, a splendid ledge of high grade ore was struck at a depth of 45 ft on last Tuesday evening. The specimens shown were certainly of a most encouraging character.

LAUREL HILL DISTRICT.—We learn that the inclined shaft of the I. X. L. has now reached the depth of 45 ft, with a body of first-class ore 3 ft in width which assays from \$200 to \$500 per ton in silver. Two tons of this ore will be taken to the Indian Quen mill in Oneota district for a trial test.

BODIE DISTRICT.—*Free Press*, July 4: In the McClintock mine during the week a ledge of fine-looking quartz came down the west side, and is dipping to the east much faster than any other ledge in the mine, except the large ledge of good ore on the 675 level (inclined). Connection has been made from the new shaft with the 500 level of the old incline, and work has been resumed on the west crosscut No. 2 of that level, which is now in 336 ft. The ground is porphyry mixed with bunches of quartz and pyrites of iron, and looks very favorable for striking the ledge.

STANDARD CON.—The new shaft has been sunk during the past week 12 ft, making a total depth of 854 ft, with no change to note in the character of the formation passed through.

UNIVERSITY.—Work is prosecuted vigorously at all points. During the week a 3 ft ledge of good ore has been cut, showing strong, clean walls.

SPARKO MINE.—The drift north from the drift is in 130 ft, having been run since last report 26 ft. The face of the crosscut is in very hard rock. The south drift on the East Summit vein is in 45 ft; progress for the week 10 ft. The ledge is 6 ft wide.

BULWER.—The south drift on the Ralston vein, 300 level, has been run 19 ft, and the south drift on the Stonewall vein 22 ft since last report. The ledge in the Ralston slopes is from 13 inches to 4 ft wide. In the Stonewall slopes the ledge is small—about 2 ft wide.

OLD MONO DIGGINGS.—*Homer Index*, June 26: A

number of miners have located quartz leads in the old Mono diggings, and some work is being done on them. The ledges are of good size, and crop out strongly in places. The ores are free milling and carry considerable gold. We understand that some parties are going to build an arrastra there to test the ore.

PLUMAS.

GOLD STRIKE.—*National*, July 3: This mine, situated at Wolf creek, is said to be looking exceedingly well. The mill is running steadily, and the property stands up to its reputation as a producing mine, in a manner extremely satisfactory to its owners. The mine, mill and houses are in excellent condition.

CURTIS.—A dry streak found in Elizabethton flat, by Loring & Leavitt last week, promises to be permanent, and very rich. Five dollars to the pan have been obtained, and several coarse, rusty pieces show that they have the old lead, which yielded so plentifully in the old workings. Loring & Leavitt have hunted the lead for years, and their tunnels, in the aggregate, will measure between 3,000 and 4,000 ft.

SHASTA.

MAD OX MINE.—*Redding Independent*, July 1: Mr. Strode of the Mad Ox mine at Whiskeytown thinks they will run their mill until the middle of July, when they will shut down for the season to make repairs and enlarge the mill dumps. The mill is crushing rich rock.

FRANKLIN GULCH.—We have been informed that that lucky miner Shafter last week crushed some 4 or 5 tons of quartz, and got the handsome sum of \$33 ounces.

SIERRA.

BLACK JACK.—*Mountain Messenger*, July 3: We learn that the company intend to start a tunnel 100 ft lower than the present one next week, and will, when this is completed, put up a 10-stamp mill. They also intend to put several concentrators into the present mill to save sulphurets, of which there are large quantities, and rich.

SAVAGE PLACER.—The tunnel has passed through the last white rock (a mixture of quartz and granite) and entered a slate formation which is much softer. The recent rich strike in an adjoining claim was made at a point about 400 ft east of the east line of the Savage Placer, in what is supposed to be an overflow from the main channel that passes down through the ridge. At a proper point in the slate rock the Savage Placer folks will make an upraise to the gravel.

TRINITY.

BUCKEYE M. CO.—*Journal*, July 3: We learn that there was a large break in the old Bolt's Hill ditch last week, caused by a tree falling in the ditch and damming the water during the night time. Previous to that the mine had been running with a full head of water, and will be again as soon as the ditch is repaired, which will be in a few days. Work on the bedrock tunnel is progressing at the average rate of 65 ft per month. It is now in a distance of 1,300 ft, and it is expected the remaining 200 ft will be run and the tunnel completed in about 3 months. The upper end of the main ditch to Stuart fork is going ahead, and the water of Owen's creek has been turned there.

ITEM.—One day this week Fred Diener pounded up a pound and a half of rock from the Monto Cristo mine at Deadwood, and obtained 2 ounces of gold, lacking only \$1.

TUOLUMNE.

OLSEN MINE.—*Union Democrat*, July 3: A 15-stamp mill, with capacity for an additional 10 stamps, will be built as soon as possible on the Tuolumne river, 4 miles from the mine. A contract for grading a road to the mill and the mill site has been awarded. About 300 tons of ore is lying on the dump at the mine. The mine is being placed in condition for stopping, which will take about 6 weeks.

ALABAMA.—The owner has commenced building a 40-stamp mill on this fine property. Mr. Harris thinks the mill can be kept at work the next 50 years, the body of ore is so great. It is low grade, but steady in its character all through the vein.

COLUMBIA NOTES.—July 3: Another big strike in quartz has been made in Columbia by La Roy Reed & Co. The ledge is of good size, and is extensive, and the Levy mine, at Wet gulch, as the place where the strike is made appears to be on a direct line with it, on the opposite (north) side of the South Fork of the Stanislaus. It is stated by our informant that in 2 days Mr. Reed has pounded out, in a hand mortar, the sum of \$3,200.

JAMESTON NOTES.—Messrs. Miller and Frank Holmes, from their mine, near Quartz mountain, have recently had 20 tons of ore crushed, yielding the sum of \$5,000. The Quartz Mountain mine, near Jameston, is reported to have been sold to New York parties.

NEVADA.

WASHOE DISTRICT.

YELLOW JACKET.—*Gold Hill News*, July 7: The Crown Point hoists through the Jacket the debris which is taken from the drift connecting the 2525 station with that mine as the work of grading down progresses. Cutting out stations on the 2525 and 3000 levels; also drifting from these stations east toward the ledge.

UNION CON.—The drift from winze No. 1 toward winze No. 2, and on the 2500 level, continues in fine quartz, some of which assays richly. The drifts northeast toward the Sierra Nevada incline, 2500 level, and south from the shaft, are both running ahead and are without change of material passed through. The drift from winze No. 1 toward the 2500 station of the Sierra Nevada incline is so near that point that connection can be easily made when needed and when the water is out of that station.

JOINT.—Crosscutting east joint with Mexican on the 1600 level to reach the line of the drift at the 1300 level of the Sutro tunnel. The joint crosscut east, 2500 level, is going ahead from 5 to 6 ft per day, and the drift north from the main drift east at the rate of 4 ft per day. These workings are in a heavy vein material and are looking well.

HALE & NORCROSS.—The winze from the 2200 to the 2400 has been opened for ventilation of the latter level of the Chollar during repairs.

UTAH.—The station set for the 2050 level of the incline is in place. East crosscut, 1060 level, in 25 ft and in good ground for progress. The ore vein lies to the east of the shaft. The diamond drill which was operated on the 1050 level found no pay ore, but developed some good prospects.

DELCHER.—The south drift, 3000 level, has been extended a total length of 438 ft, and discontinued on account of heat. The drift north is within 40 ft of the Crown Point line and making good progress. Its connection with Crown Point workings will give needed ventilation.

THE NORTH DRIFT.—The drift north at the 1300 level is in 90 ft, and in low-grade quartz which gives promise of something better near.

COS. VIRGINIA.—Running south on the 2300 level and toward the Best & Delcher winze. This winze will be continued below the 2000 level some time this week. Extending east crosscut No. 1 at the rate of 5 ft per day.

SURRA NEVADA.—Still running west on the 2300 level toward the line of the main drift; total length of drift, 255 ft. The north drift, 2400 level, is 905 ft in length, and making good progress along the vein.

BEST & DELCHER.—Chambering out on the 2000 joint with Con. Virginia for a winze to the 2300 level. Sinking will be commenced this week.

NEW YORK.—The drift north and south along the vein on the 1000 level promises well. The quartz continues clear and kind, but mostly less than milling grade.

QUINN.—Raising from the 200 level toward the old shaft, also sinking in that shaft. When connection is made the 200 level will be thoroughly prospected.

SUTRO TUNNEL.—South header stopped for the present; total length 2703 ft. North header running rapidly on; measurement for the week just made in time for this issue, but is about 3,650 ft. Track for air motive nearly completed up to the point where the drain boxes are above the floors of the tunnel.

AURORA DISTRICT.

REAL DEL MONTE.—*Esmeralda Herald*, July 3: The work during the past week has been concentrated in sinking the main shaft. Good progress has been made, about 20 ft being accomplished. The formation grows less broken as depth is acquired.

THANKSGIVING.—There is no material change in the character of ore being taken from this mine, except, if anything, it carries more metal. The mine is looking better every day in point of permanency, and the more it is developed the wider the ledge grows.

LORENSBURG.—This property is located on Last Chance hill, and is owned and being worked by T. W. Gupit, who is taking out some very fine rock for milling. In early days this mine was known as the Heath.

EXCELSIOR.—The tunnel is now in 316 ft, 43 ft having been run the past month. It is calculated the tunnel will tap the ledge at a depth of 150 ft below the surface. Several strings of quartz have been cut, carrying more or less metal.

CORTAZ.—William Pool is still peering away on the Cortez, taking out ore. This is a splendid mine, and will come to the front boldly one of these days.

THE PROSPECTS.—Work on the tunnel and shaft progresses with favorable results. Yesterday some fine ore was taken out.

BRISTOL DISTRICT.

HILLTOP CO.—*Pioche Record*, June 25: The Mendia, of the Hillside company, is now shipping to the furnace 32 tons of ore per day, the number of teams hauling being increased to 13, and capable of bringing in enough ore to keep the furnace in steady operation for some time to come. The Hillside has been improving the past few days, especially on the 5th level east, 380 ft from the incline, where a large body of heavy lead ore has been encountered, which looks very promising.

NOTES.—We understand that the mine will be renewed on the Mayflower mine, of the Bristol silver mining company, the coming week. The furnace is running well. Ore has been scarce on the dump, but is now coming in fast.

COLUMBUS DISTRICT.

NORTHERN BELLA.—*True Pioneer*, June 20: The usual amount of ore is being taken out and shipped daily to Belleville. One of the mills has been shut down for the past 3 days, and will probably remain idle 3 days longer, when it will be started up again in good working order. The mine is looking as well as usual.

MOUNT DUBLIN.—The main shaft is now down 74 ft below the 245 level. The east drift on the 3d level is in 108 ft, and is now in good running ground. On the 2d level the east drift is in a distance of 213 ft, and the rock is extremely hard. The west drift from crosscut No. 1, following the vein, is in 47 ft. The face of this drift is in fair milling ore. The east drift from crosscut No. 1 is in 39 ft and in high-grade ore. The ore dump contains now 125 tons, which will mill from \$150 to \$200 per ton.

NEW YORK.—This week a 9-ft ledge has been struck, carrying \$124 per ton. Much depth has yet been attained, but by next week work enough will have been done to determine something of the real value of the find.

LUCKY HILL.—The incline has made 10 ft progress during the week, the total depth now being 140 ft. It is in ledge matter all the way. Chloride and manganese are coming in on the footwall.

GENERAL JACKSON.—The new whim works well, and headway is being rapidly made. A crosscut has been started north from the bottom of the incline, and has now reached a distance of 20 ft. The crosscut is all the way in ledge matter, and the face is ore.

THE O. K.—Work has just been commenced on this mine, and at a few ft from the surface the ore assays \$210 and \$180.

EUREKA DISTRICT.

HODGSON MINE.—*Sentinel*, June 30: The Hodgson mine in Secor county, will be worked energetically this season. In the first excitement which rushed the White Pine miners over this way, it was the wagons which carried ore from this mine to the mills at Hamilton, which they followed back. It was rich and extensive bodies that were opened up. Other excitement took attention away, but now the owners, the Hodgson Bros., propose to see what is below the croppings.

TOWNSEND CO. GAZETTE.—These mines, north of Adams hill, at a depth of 80 ft, have struck the footwall, and will immediately commence drifting for the pay streak in the ledge matter. This property is eligibly situated, and the ore is of high grade. We would not be surprised if it proved dividend paying, and that before long.

EL DORADO.—The ore in this mine is improving in extent and quality as it is being opened up, and now shows a broad about 10 ft wide. The ore is a rich chloride, and assays from \$315 to \$346. Mr. Riley has about 40 tons on the dump, and as soon as connections are made with the ore chamber, a number of men will be employed, and regular shipments made to the smelting works.

EUREKA TUNNEL.—The contractors in the Eureka tunnel have been making good headway during the past 10 days, and has the tunnel now in 1,200 ft. The last 20 ft has been run through belt of red shale, the face of the tunnel being in the same formation. Everything indicates that the main ledge will be cut before many more ft have been run.

LIDA VALLEY DISTRICT.

MINING NOTES.—*Cor. Esmeralda Herald*, July 3: James Andrew, late of Candelaria, recently purchased the Gold Mountain mill, and will start it up as soon as a supply of wood can be secured. R. H. Stewart will start up the Lida Valley mill, and Aug. 1st. At Tulare canyon, within the last few weeks, a "dry washing" machine for placer mining has been introduced, which is spoken of highly.

NEWARK DISTRICT.

BAY STATE MINE.—*White Pine News*, July 1: Supt. McGrath, of the Trench, received a dispatch Tuesday evening from Supt. Thomas Winslow, of the Bay State mine, at Newark, announcing that a rich and extensive bonanza had been struck in the latter mine. The Bay State has already produced much rich ore, and bids fair to become one of the most valuable mining properties in eastern Nevada.

PARADISE DISTRICT.

PARADISE MINE.—*Reporter*, June 20: The Paradise mine never looked better. There is an abundance of good ore in sight, and are long we predict this mine will be classed among the dividend-paying mines of the State.

BULLION.—This mine is again coming to the front, with the very best of prospects. The mill is running regularly on good paying tailings, and they have struck a large and very fine body of ore in the mine, and the vein is rich and quantity of ore is being hauled out.

NOTES.—There is quite a number of other good prospects in the camp. Among them we may mention the Glory, Mount Rose, Wild Goose and Mary Wilder; upon all of them work is being vigorously prosecuted.

OSCEOLA DISTRICT.

MIXING NOTES.—*Cor. White Pine News*, June 23: The mill is now running in good shape and the mines are developing well. The recent striking of the north and south channel, in our placer grounds, has caused quite a rush among the placer miners, and about 500 acres of ground have already been located upon the supposed course of the channel, and the parties making such locations feel very confident of the value of their ground.

WILLOW CREEK DISTRICT.

ANOTHER DISCOVERY.—*Silver State*, June 23: We have been informed that prospectors have discovered a rich ledge 6 miles north of the Ohio mine, on Willow creek, and have started to work it. They found float gold from the ledge some time ago, and traced it up by running out until they finally found the lead, which is said to be very large.

ARIZONA.

TOMBSTONE DISTRICT.—*Cor. Tucson Record*, June 30: In the Contention they have struck quite a body of ore running north on the 102 level as well as struck the ledge at the 312 level. This mine is looking well and must have about 500 tons of ore developed.

HEAD CENTER.—The vein in this mine has been tapped at the 310-ft crosscut, it was found rich in free gold and horn silver, being the same character of ore found at the 270 level. The 210 level is to the north 340 ft from the working shaft, and is still being driven ahead in good milling ore. This same level is in the south 112 ft and assays from the face of the drift average over \$300 to the ton.

GLOBE DISTRICT.—*Silver Belt*, June 26: The Nugget mill is now ready to run and has a supply of 1,000 tons of assorted ore on the dump, which is expected to yield not less than \$200 per ton, besides about 2,600 tons which will average between \$50 and \$80.

MIXING NOTES.—Another extensive strike of exceeding richness is reported in the Stonewall Jackson. The Chamberlain mine is showing a strong vein of milling ore. This mine is regarded as one of the best mines of the district. The Chromo is producing well. The proprietors have about \$6,000 of their best ore sacked. The Hartford, the property of J. L. Clark, shows a strong vein which assays \$100. The Diana, near the Hartford, a 4-ft ledge assays from \$10 to \$400 per ton. The ore is carbonate and bears a strong resemblance to the frene.

ARIZONA DISTRICT.—*Tucson Record*, June 26: The Con. Arizona, the largest mine in Arizaca, is now being opened up. They have the hoisting works in operation taking out the water preparatory to pushing down developments.

ITEMS.—The Dick Orant mine is down about 20 ft and with about 4 ft of high grade ore. The Peacock is down 100 ft, and levels are being run off and are showing good ore. The Silver Eagle is pushing work as rapidly as can be done by hand, and are grading for hoisting works. There are a good many men at work on this mine. Both mills are running and turning out a good deal of bullion.

BIG BUE DISTRICT.—*Arizona Miner*, June 26: Mr. Houghton, engineer of the Valley Forge Co. M. Co., arrived at Big Bue on Friday last and at Prescott to-day. He intends to put up the quartz mill of the company, while he is on the ground, and commence the production of bullion. He has examined some of the mining properties belonging to the Valley Forge people, and is much pleased with the prospects. Money, machinery and mines this company possess, and it is only a question of time when they will send forth large yields of bullion.

COLORADO.

BOULDER COUNTY.—*Caribou Co. News*, June 25: At present the Caribou has to show a splendid shaft house, 50x100 ft, with probably the finest hoisting apparatus in Colorado, embracing two friction spools, 60-horse power engine, etc. Its main shaft is fully 300 ft deep, with drifts innumerable. It is working about 50 men, under Supt. E. B. Smith. The ore is all treated at its own mill at Nederland, six miles below this point, by the chlorination and amalgamation process. This weekly shipments of bullion mounts always into the thousands.

SILVER STAR.—This mine is near the Caribou, and the main shaft is 500 ft deep with many drifts at various levels. The output of excellent ore is large.

SHERMAN.—At a depth of 110 ft a tunnel level has been worked 100 ft along the vein and produced about \$250,000 in money. From this level they sunk the shaft, on good mineral all the way, and the mine is now in capital working order.

CO. COUNTY.—*Cor. Georgetown Courier*, June 26: The Republic lode has a 200 level and a 75 level, which show an ore vein from 10 to 12 inches thick, composed principally of galena and copper pyrites carrying silver and gold. They have also just struck ore in the lower level, having run a crosscut 125 ft to the lode. About 100 tons of ore has been taken out, the most of which was shipped to Black Hawk and milled from 100 to 125 ounces in silver per ton. The quantity of timber handy to the mines, and no trouble from water.

IDAHO.

CARBON DISTRICT.—*Enterprise*, July 1: Two years has produced a wonderful development of fine gold veins in this camp. The Robinson, Oneida, Northern Light, Iowa and others, besides a dozen or more other prospects on the main Carbon mountain are the equals of the best mines yet discovered, and when mills are set in operation, we may expect a grand boom in this region of country.

IDAHO CITY ITEMS.—*World*, June 30: The Golden Fleese Co. is still pushing work ahead on the mine. Two drifts have been run east and west on the vein from the face of the tunnel, and good ore is being extracted. Each drift has been extended 45 ft. Stopping will soon be commenced.

MONTANA.

BANSOCK DISTRICT.—*Atlantis*, June 23: Among the new developments recently made up Graceland copper creek, we note the Flagstaff ledge. They have followed a very rich crevice of ore between well-defined lime wall rock, which has widened from almost nothing to 10 inches. It assays \$438 to the ton, \$304 in silver and the remainder in gold.

GRANDLIFE ITEM.—Ore is now so plentiful in the mines here that 1 man is taking out as much as 16 others can have done some time ago. The way and strength is now sight to run the old and new furnaces for 2 years hence, at the rate of 100 tons per day, yielding \$140 to the ton.

YELLOWSTONE PARK.—A town named Cooke City has been laid off on Soda Butte creek, Yellowstone park, where Jay Cooke, T. W. Bates and others are preparing to put in extensive workings. The initials of the new smelting company are E. M. M. & S. Co. A large force of men is to be put to work.

UTAH.

TOLE COUNTY.—*Cor. Salt Lake Tribune*, June 26: The district of Stockton is livelier than for a long while, and Gen. P. E. Connor has made a great change about the Longmaid smelter, and he is laying a solid foundation for a permanent and successful future. The working of the ore now being extracted in large quantities from the Great Basin mine, which to-day is one of the most valuable mining properties in the Territory.

SUMMIT COUNTY.—*Park City Co. Salt Lake Tribune*, June 26: The Ontario has stood out prominently for years as one of the best mines on the face of the globe. Although vast quantities of

Utilization of Additional Species.

[BY W. N. LOCKINGTON.]

New Sources of Food.

Advance in civilization is marked by an advance in the choice of food. In the words of Spencer, "There is an analogy between progress in bodily nutrition and progress in mental nutrition. The higher types of mind, like the higher types of body, have greater powers of selecting materials fit for assimilation."

As there is room for much further advance in mental nutrition, so is there for much advance in bodily nutrition. The choice of food has hitherto been determined empirically. Prejudice is the usual guide. A few experiment with foods, and finding some hitherto unused or little known article to be exceedingly nutritious, or to supply a want, they recommend its adoption, but either their recommendation is unheeded, or the new article wins its way into favor with exceeding slowness.

The multitudinous forms of animal and vegetable life could furnish us with many an article of food equal or superior to those in use. We have not yet been through the full range of nature in our search for food. Yet our wide-spreading commerce has made us familiar with many foods that were formerly unknown, so that, prejudiced though we are, our range of food is wide compared with that of our ancestors, or that of a savage, but almost all the plants we grow for food purposes, as well as almost all the animals we eat, are, if not those used by our own ancestors, those which have been used for ages by other peoples with whom we have come in contact. It is the same with animals and vegetables used in the arts. We have adopted them from others—few indeed have had their merits discovered and utilized.

The seed of certain grasses and certain leguminous plants have for thousands of years been the chief sources of nutriment procured by man from the vegetable world, and they fulfill his purpose well; but the two immense orders of *Leguminosæ* and *Gramineæ*, the latter entirely, the former chiefly composed of plants that are adapted for food, could furnish many additional species that would not only vary our dietary, but give us a supply or food under conditions that preclude the growth of species now in use. The number of fruits cultivated might be greatly increased. Almost every section of country furnishes some nut or berry which even in its wild state is pleasant to the taste.

What might not cultivation do for some of these. It has given us all the varieties of plum and cherry, apple and pear, from sour and unpromising originals, and the long category of vines from one European species. Many edible roots, stems and leaves have yet to be discovered or improved into value.

A few species of the order *Cruciferae* are eaten, while the rest are neglected. Yet the whole order is good for food. A botanist could multiply examples throughout the range of vegetable life, but it will suffice here to give one more; the mushroom or fungus tribe, so little known, so much dreaded, yet containing so many edible species. Again and again it has been shown that the same amount of observation which enables a man to distinguish night-shade from the potato, or carrots from hemlock, would enable him to discriminate between the poisonous and edible mushrooms, yet only an enthusiastic hand ever dares to venture beyond the conventional species. The species favored by the Anglo-Saxon is in ill-favor with the Italian, who has a wider range of edible fungi, as have also the Frenchman and the Russian.

As mushrooms can be grown in places where ordinary plants will not flourish, an increased taste for and knowledge of them would be of great benefit to our poor. If from the vegetable world we turn to the animal, we find prejudice and ignorance still more rampant. The Mosaic law is still obeyed in this matter by nations who break it in most others.

The ordinance which restricted the Israelites to the use, for food purposes, of such quadrupeds only as chew the cud and divide the hoof, was in the then state of knowledge a wise and safe one.

All such animals are herbivorous, and are better fitted for food than carnivorous mammals. They are of large size, furnish an abundance of healthy muscle, and have in many instances been domesticated for ages. But numerous other large animals are herbivorous also, and extensive series of small animals are graminivorous or frugivorous, devourers of seeds or fruits. Why should not these be eaten? The omnivorous pig, whose diet, at least in a state of domestication, is not particularly choice, and whose flesh is less nutritious and less wholesome than that of most other mammals, is largely eaten by man, yet the prejudice against horse flesh is almost universal among Aryans.

We occasionally eat a hare or rabbit, but the rest of the rodentia, mostly seed or root-eaters, are neglected. The ground squirrels, a plague on the Pacific slope of the United States, would cease to be so were man to make a systematic onslaught upon them to gratify his taste. Their flavor is pronounced excellent by all who have tried them. The taste for this or that particular article of food is to a great extent acquired.

Many who ultimately become fond of oysters dislike them at first. The same remark holds

true of many other foods in common use. The muscles of all birds and mammals are suitable for food when in a perfectly healthy condition. More care is necessary in the case of carnivorous mammals, since their flesh decays more rapidly; yet it is doubtful whether one person in ten could distinguish cat from rabbit were they cooked alike and the more tell-tale portions removed.

The strong or fishy flavor of marine mammals and birds would doubtless be objected to by those whose gustatory nerves had learned to relish high game and Limburger cheese, yet as safe sources of nutriment they would at least be superior to the former.

Civilized nations of Aryan descent devour many mammals and birds, some batrachia and many fishes; but the intervening class of reptiles is almost wholly ignored. Why? Simply because of the pious horror of the snake. Lizards, as they have long tails, are viewed only a little less unfavorably, while tortoises—thanks to their widely different form—are accepted with some reservation; yet the flesh of snakes and lizards is as firm, as nutritious and as healthy as that of fishes, if not more so; and those who have eaten them when among peoples who do not share our prejudices, have had their own shaken. The Frenchman, who is a good cook, eats frogs; the Englishman cannot conquer his prejudice.

Leaving the vertebrata; the choice made by civilized nations among the invertebrata is highly eccentric.

A Spaniard or Frenchman relishes a cuttle fish, which an American or Englishman shudders at; and the harmless snail and slug, *per se* as good food as oysters, are esteemed by some nations and detested by others.

There is little doubt that the great majority of molluscs of sufficient size are healthy food, and that man has yet to discover among them many a *bonne bouche*.

Descending lower still, sea-urchins, sea-anemones and sea-cucumbers are eaten by some highly civilized nations, and who can tell how acceptable they might prove to an Anglo-Saxon could he but conquer the horror he feels at their appearance.

P. H. Gosse, so well known for his interesting works on natural history, tells us how he cooked the common sea-anemone of the English coasts (*Actinia mesembryanthemum*), and how fond his little one became of it, asking for "more tinnies."

Probably the classes of animals which are of least value as food to man are those included in the sub-kingdom, Arthropoda, namely, insects, arachnids, myriapods and crustacea, the multitudinous types grouped together as *Vermes*, or worms, and the uni-celled organisms, or Protozoa. Some of the larger crustacea, known as crabs, lobsters, crayfish and shrimps, are eaten as delicacies, and it is probable that many other species are equally edible, but the vast majority of the class is only of value to man inasmuch as it furnishes food for larger marine animals.

Insects are eaten by many wild tribes. Some of the Indians of the Pacific coast find in the abundance of grasshoppers that plague the white man, an abundant store of food. Similar Orthoptera are largely consumed by the natives of South Africa, and those of some of the Sunda Isles esteem dragon-flies a great delicacy, catching them, according to Wallace, on bird-lined twigs. Though there can be comparatively little nutriment in the soft bodies of insects, yet there is no reason for the horror with which they are regarded, as articles of food, by the Aryan races. A fancy for the flavor of the Rocky Mountain locust would go far toward decreasing the devastation of that dreaded pest.

Some of the marine worms are accounted delicacies by certain tribes, but the greater part of the varied forms belonging to the sub-kingdom must be regarded, so far as they are useful to man at all, as only indirectly so through their consumption by animals he feeds upon. The same may be said of the Protozoa, which, swarming in countless numbers in sea and river, lake and marsh, furnish food for the creatures above them.

Putting aside all question of protection or preservation of plants and animals now used as food, the examples adduced are sufficient to show that the range of foods might, with advantage, be greatly extended.

Much remains to be learned respecting the diseases and bodily states of cold-blooded animals and of the invertebrata before we can use them for food with the same confidence with which we eat beef, mutton or poultry. The diseases of the higher animals are, to a great extent, similar to our own, and we have learned how to discriminate; but we do not recognize the diseases of fishes, crabs and shell-fish. The stories of poisonous fish probably arise from this source. Every year we hear of cases of poisoning, well authenticated, from eating mussels, lobsters or other crustacea, or mollusks, which are usually healthy food. All these creatures are subject to diseases which we have not yet studied, and it may be that at certain seasons, such as immediately after reproduction, some of them are unfit for food. This is one well-grounded cause of prejudice, but one which will be removed as our knowledge of the lower forms of life extends.

New Sources of Useful Materials.

The animal and vegetable world furnish us with other things besides food. Materials of other descriptions furnish, by their manufacture, a means of procuring food to some, while the articles manufactured are of use to all. Commerce, which has made us familiar with foods previously unknown, has helped us still

more in this direction, yet when we consider the great variety of vegetable and animal life, we cannot but believe that much more remains to be discovered, or, at least, utilized.

Other nations, many of them but semi-civilized, others barbarous, have, in these things, been our teachers. As maize and potatoes were known to the Indians before we learned to use them, so was *Phormium tenax* to the Maoris, and cotton to the Hindoos and Chinese.

When it is remembered what vast industries depend upon the supply of fibrous plants, and that a fiber with different qualities, as it could be applied to new uses, would start a new branch of trade; when we see how extensive are the manufactures carried on from gum-resins like caoutchouc, or gutta-percha, we must acknowledge that the discovery of a fiber or a resin with new uses would furnish a livelihood to many additional workers. Take paper for example. Until lately this article was made from linen rags, but as the supply of that material fell short of the demand; cotton waste, straw, the Yucca plant, and other vegetable materials came into use, and it is evident that it can be made from almost any fibrous substance reduced to a pulp. Few are the plants that cannot be utilized by man. If valueless for food or for building purposes, a fiber, a gum, an essential oil, a medicinal product, may be found in most.

The constantly-increasing stock of geographical and botanical knowledge brings new materials into the notice of scientists, and the constantly-increasing needs of mankind brings them slowly into public notice. The secretion lately found in Arizona, upon the branches of *Larrea Mexicana*, and of another plant, may yet enable us to dispense with the imported lac from Asia. Chemically the two seem identical; practically the despised Indian, here again our teacher, has long ago proved its use in the mending and making of vessels for cooking purposes.

Here is a case of a new material furnished by the animal kingdom, for it appears almost certain that the secretion, like that of wax or honey, is elaborated by the insect from the juices of the plants it feeds upon. Insects, so little used for food, so terribly destructive to our food plants and annoying to our domestic animals, may yet yield to us many useful materials; may yet prove in this respect among the most useful of organisms. Silk, honey, wax, gum-lac, cochineal, all are insect products, elaborated by insects from plants; and the last two are the produce of *coccideæ*, those destroyers of our orchards and oranges. Does not this point a way to the utilization, in some cases, of our insect pests?

The higher animals may not furnish us with many additional materials. Horn, hair, fur, wool, hides, feathers, bone, ivory, have their known uses. Improvement here is to be looked for rather in new uses for known materials than in the discovery of new ones. But the lower animals may yet yield us many useful substances. The great treasure house of the sea holds more than we have yet learned the use of. Shells, corals, the horny axes of soft-corals, and many other portions of marine animals, may be utilized for something more than show; and other secretions may be found as useful as those of the sepia. But though the number of useful species—useful either directly or indirectly—is so large that it includes probably the greater portion of existing organisms, yet some are far more useful than others, and some are directly injurious to more useful organisms. Such species need not be cultivated, except where they do not come into direct competition with more useful ones; but their consumption or use by man would diminish their numbers and give room for the more useful forms, which are now often permitted by man, even in his own cultivated fields, to be crowded out by the less useful.

A MOUNTAIN OF OBSIDIAN.—Near the foot of Beaver lake, in the National Park of Yellowstone, a recent party of explorers came upon a remarkable mountain of obsidian or volcanic glass, which rises in columnar cliffs several hundred ft. in height. As it was desirable to pass that way, the party had to cut a road through the steep glassy barricade. This they effected by building huge fires on the glass to thoroughly heat and expand it, and then dashing the cold water of the lake against the heated surface so to suddenly cool and break it up by shrinkage. Large fragments were in this way detached from the solid side of the mountain, then broken up small by sledge hammers and picks not, however, without severe lacerations of the hands and faces of the men from flying splinters. In the Grand canyon of the Gibson river, the explorers also found precipices of yellow, black and banded obsidian, hundreds of ft. high. The natural glass of these localities has from time immemorial been dressed by the Indians to tip their spears and arrows.

INTENSE COMPETITION.—The most remarkable exhibition of the capacity of the foreign importers to compete for the trade of the whole interior of the country was afforded by the demand of an Iowa member of Congress for the remission of the import duties on foreign salt used in curing beef and pork in that remote Western State. This foreign salt hears all the cost not only of the transit across the ocean, but also that by rail from the seashore to the frontier, a distance of a thousand miles.—*North American*.

Progress in Bodie District.

One of the evidences of increased confidence in Bodie, says the *Free Press*, is the fact that new and more extensive works are constantly devised and added to those already in operation. The managers of a group of mines, comprising the Noondays, Red Cloud, Oro, Concordia, Maybelle and Paris, have adopted a plan for the draining of those mines which is at once economical and sensible. The companies named will contribute pro rata for the sinking of one large shaft. The shaft of the Red Cloud, which is now 400 ft. deep, has been selected, and will always be kept deep enough to drain the group. Already the work of enlarging the Red Cloud shaft has been commenced, and is in progress from the 400, 250 and 125 levels. In about six weeks it will be completed, with three compartments, two for working purposes and one for a pump. Thereafter the shaft will be steadily kept going down for an indefinite period—certainly until a depth of 1,500 to 2,000 ft. is attained. The fine Corliss engine, now in use at the Noonday mill, will be transferred to the Red Cloud shaft and utilized as a pumping engine. Beside this co-operative work, there are other signs of progress in the district. The Noonday mill, which has now 30 stamps, is to be increased to 40; and the Bodie tunnel company is about to build a mill of perhaps 20 stamps, in order to reduce its own largely increasing ore. At the Belvidere new and more efficient hoisting works are near completion; the Syndicate company is putting an engine and hoisting machinery in the tunnel about 2,000 ft. from the mouth; and the Glynn-Dale company is erecting new machinery on its ground. These costly preparations for extensive and systematic mining are the best indications of the confidence which men of capital repose in the future of Bodie. Besides this they are generally cheering.

RICH QUARTZ IN SHASTA.—We learn from a late number of the *Shasta Courier* that work on a number of the claims on the great Iron Mountain gold and silver lead is progressing as rapidly as circumstances will permit. The mines have been difficult of access, situated as they are high up on a rugged mountain, but the completion of Camden, Magee & Co.'s Shasta and Iron Mountain grade, which is almost, if not quite completed, will greatly improve matters in that respect and facilitate operations in future. All the work done on the great lead so far only serves to increase the belief in the almost fabulous richness and the vast extent of the truly wonderful ledge. Innumerable assays have been made from ore taken from various locations extending for a distance of over five miles, and the result is all the way from \$40 to \$550 to the ton. Many of these assays have been made by the best assayers in San Francisco, and those made there correspond with results reported by other assayers who operated on portions of the same ore. Prospectors and mining operators continue to wend their way through our town hound for the mountain of promise, the fame of which is rapidly spreading through the land. And no wonder its fame is extending. Just think of a gold and silver-bearing ledge varying in width from 20 to 1,000 ft., and plainly traceable by croppings along the mountain for a distance of seven or more miles, and the rock assaying as above. Why the very idea of such wealth is calculated to make the misers of the world go crazy, and even the sleepy fogies of the old town of Shasta jump up and howl with delight.

A PRODUCTIVE MINE.—The Ontario mine, in Utah Territory, is one of the most valuable mines on the coast. Over two years ago it paid the first dividend, and has paid them with delightful regularity ever since; and it is reported that enough ore for another year's dividends is at the miners' hands. The vein of the Ontario is about four feet thick, and carries ore which yields an average of \$100 per ton. The deepest level in the mine is 600 ft., but the 700 will soon be opened. The ore is said to be refractory, but is very skillfully manipulated. The company's works are extensive and thoroughly complemented. After the ore is pulverized in the powerful 40-stamp batteries it is subjected to a chloridizing roasting in two Stetefeldt furnaces, and the percentage of chlorination of the peculiar ore is relatively high. The roasted ore is then amalgamated.

GROWTH OF OUR MANUFACTURES.—The hands employed in this country in the production of agricultural implements now number 40,680. Maine has 282; New Hampshire, 245; Vermont, 495; Massachusetts, 646; Rhode Island, 108; Connecticut, 790; New York, 7,237; Pennsylvania, 3,097; Delaware, 71; Ohio, 10,248; Michigan, 1,938; Indiana, 2,536; Illinois, 7,870; Wisconsin, 2,700; Minnesota, 330; Iowa, 1,104; Missouri, 1,074; Kansas, 261; Nebraska, 81. In 1850 the country had 5,361 hands engaged in this branch of industry. In 1860 the number had increased to 12,867, and in 1870 it had reached 23,251, or over 17,000 less than the figures of to-day. Ohio shows the most decided advance of any State, her employed being only 165 in 1860, while this year, as shown above, there are 10,248.

IN May the Stormont mine in Utah produced \$54,000. It said the reserve in this mine warranted the expectation of a production of \$50,000 to \$60,000 per month for some time, and that dividends will probably be resumed in August on a more liberal scale than last February.

THE ENGINEER.

A Wonderful Little Steamer.

A St. John's (N. F.) dispatch, dated the 22d of June, says: The little steamer *Anthracite*, which left London, via Falmouth, England, 18 days ago, on a voyage across the Atlantic, arrived at this port yesterday. She is the smallest vessel that ever steamed from Europe to America. Her total length is 84 ft., beam 16 ft., and depth 10 ft., her engine and boiler room being 22 ft. 6 inches. Her gross tonnage is 70.26 tons. The voyage was undertaken for the purpose of testing the capabilities of the Perkins system of high pressure engines, and the success that has thus far been achieved by the little vessel is likely to lead to a revolution in marine architecture. Throughout the entire passage the weather was unusually boisterous, and there can be no doubt that under more favorable circumstances the time of the little ship would have been much better.

The economy in the consumption of coal and water effected by the use of the Perkins system of boilers is something wonderful. Only 20 tons of coal were consumed by the *Anthracite* on the trip across, and 436 gallons of water. The Perkins system consists of a tubulous boiler, in which the steam is generated at an exceedingly high pressure. By means of a special system of engine this steam is used and reused over and over again. The boiler is constructed of horizontal tubes, welded up at each end. These horizontal tubes are connected by small vertical tubes, and the boiler is proved to 2,500 lbs. per square inch. In the engine there are three cylinders, of different diameters: 8-inch, 16-inch, and 23-inch diameter respectively, with 15-inch stroke. The smallest one is placed over that of medium size, and worked from the same piston rod. The engines are of 20 horse-power nominal, and 168 horse-power indicated. The high-pressure and medium cylinders are single acting, the low-pressure one being double acting.

The *Anthracite* intends to leave as soon as possible for New York, in order to give a practical exhibition to the engineers and others interested in such matters in the United States of the benefits and advantages of the Perkins system. The captain and officers of the little craft profess to be abundantly satisfied with the results of the voyage.

AN IMPROVED system of constructing and driving piles, lately introduced in London, seems to have proved quite successful. According to the *Engineer*, these piles, which are tubular, can be made of either cast or wrought iron, and the thickness of the metal can be proportioned to suit the varying circumstances of construction; the lower end of the pile is made solid and pointed, is generally of wrought iron and steel tipped; the piles are also formed in sections, screwed together by strong steel sockets or joint covers, which are barrel-shaped on the outside, in order to diminish friction when being driven. Instead of blows being delivered on the head of the pile, the driving force is expended just where it is needed, namely, at the point, and this result is attained by using an elongated cylindrical driving weight, which travels easily inside the tube; the weight is raised by means of ropes or rods, and is allowed to fall on the flat head of the solid point, the pile thus forming its own guide for the driving weight. The effect of each blow is to drag, rather than drive the pile down; the point is swelled, and of sufficient diameter to effect a clearance for the joint covers, which have to follow it down, the whole operation being one of entire simplicity.

CAPT. EADS' SHIP CANAL.—A late Washington dispatch says: Capt. Eads arrived here this morning, and after a conference with his friends has decided to continue the perfection of his arrangements for carrying out his great project of connecting the two oceans. From conversation with the members of the committees of both houses, he is satisfied that next December they will be ready to take definite action respecting this great enterprise. In the meantime the government will be in possession of more satisfactory information from the United States of Colombia, and will have doubtless succeeded in completing negotiations which will enable the government to extend such aid as may be necessary to insure the completion of the work. Capt. Eads goes from here to New York, where he will confer with a number of prominent capitalists, who are entirely willing to embark in the project, being satisfied that Capt. Eads' experience and great engineering skill is a sufficient guaranty that the work can be accomplished at a cost less than that asked for by his bill.

ECONOMICAL ENGINEERING IN THE ST. GOTTHARD TUNNEL.—Collado enumerates the following advantages from the use of his compressor: 1. A saving of more than 600,000 francs (\$120,000) in the simple purchase of compressors. 2. The reduction of the cost of buildings to about one-tenth of what would otherwise be required. 3. A ventilation so complete that the ventilating fan, which had been previously purchased, are entirely useless, and their whole cost might have been avoided.

USEFUL INFORMATION.

Dynamite for Removing Stumps.

A correspondent of an English agricultural journal gives the following account of his use of dynamite for removing stumps of trees felled in a park at Meantmore, Bucks, in order to improve the landscape and leave more room for the rest of the trees to develop themselves:

The only tools required are an earth auger, which is similar to an old-fashioned wood auger, two inches diameter at the bit end, about four ft. long, and fitted with a slightly hollowed shield or cap, which the man fits against his chest when boring (this is used for boring holes between the fangs), a crow-bar, a grafting and a stock ax. Suppose a large root is to be removed out of the ground: a bole is made with the earth auger between two of the strongest fangs; this is put in at an angle, so that the bottom of the hole is as near under the center of the root as is possible. The hole is then charged with a few cartridges of dynamite; according to the size and strength of the root; a primer cartridge, containing cap and fuse, is then inserted on the top of the charge, and the whole rammed down with loose earth by a wooden rammer. The end of the fuse is then lighted; this explodes the cap, and that in its turn the dynamite, and the whole mass is usually blown out, breaking the root into convenient pieces for loading up or burning. The fuse is cut off at sufficient length so as to allow the workmen to get out of danger, which is usually from 50 to 100 yards, according to the strength of the charge. After the charge has exploded, seldom anything remains but a large hole, much resembling the head of a boiler. I took particular notice that no damage whatever was done to the surrounding trees. We had nearly 400 roots got out by this process, and with two of our common laboring men, with one man sent by the agents of the dynamite company, we have been able to remove from 25 to 30 per day of roots averaging from a foot and a half to four ft. and a half in diameter. I find from careful calculations made that we have been enabled to remove the roots in a far more expeditious manner than hitherto, and at from 50% to 60% less cost. No one need be prevented from using dynamite on the score of its being dangerous, for with ordinary care it is, in my opinion, as safe to use as gunpowder.

SPONTANEOUS COMBUSTION.—Some experiments made at Riga with reference to the spontaneous combustion of various materials, wadding, raw flax, hemp, the waste of silk, wool and cotton spinning, also sponge, as well as the wood dust found in the cabinet-makers' shops, appear to demonstrate the important fact, among others, that small quantities really take fire sooner than large ones. The substances named were saturated with various fluids—oil, turpentine, petroleum, various varnishes, etc., all the fibrous materials took fire when saturated with any of these oils, or with mixtures of the same; sponge and wood dust, on the contrary, proved to be entirely harmless. Combustion ensued most rapidly with 17 grains of wadding and 67 grains of a strong oil varnish, namely in 37 minutes; while 200 grains of washed cotton waste, of which a portion was saturated with 750 grains of strong oil varnish, and the remainder wrapped about it, required a period of well-nigh 14 hours. On these materials being placed in a well-sheltered spot, and subjected to a heat of from 18° to 40° C., silk did not flame up, but slowly charred; and, as already mentioned, small quantities seemed to take fire sooner than large.

DUST FIRES.—A gentleman at Appleton, Wis., communicates to the *American Miller* his experience, which shows, as we all know, that other kinds of dust besides flour are explosive under certain conditions. He says: The loft of my spoke mill, in this city, was wholly used as a finishing room, where the spoke was finished, and polished by contact with rapidly revolving sanded belts. As it was a square or box stove, used for warming purposes. The light, fine dust would accumulate in every crack and crevice of the room, requiring cleaning off every day. One day some of this dust was seen to fall from a rafter upon some live coals that had accidentally got out upon the hearth of the stove. Instantly there was a flash that filled the whole loft, and it was on fire in a hundred different places. It was with the most active exertions that the fire was subdued, and not without a considerable damage to the building and stock. I believe the air was strongly impregnated with gas evolved by friction; and that the explosion and fire occurring in flour mills are precisely of the same nature and due to the same causes.

HOW TO TELL A HORSE'S AGE.—The editor of the *Southern Planter* says: The other day we met a gentleman from Alabama, who gave us a piece of information as to ascertaining the age of a horse after it has passed the ninth year, which was quite new to us, and will be, we are sure, to most of our readers. It is this: After the horse is nine years old a wrinkle comes in the eyelid, at the upper corner of the lower lid; and every year thereafter he has one well-defined wrinkle for each year of his age over nine. If, for instance, a horse has three wrinkles, he is 12; if four, 13. Add the number of wrinkles to nine and you will always get at it. So says the gentleman, and he is confident it will never fail.

HEATING CITIES BY STEAM.—The Boston *Journal of Commerce* is in favor of steam heating, and for these among many other reasons: "The cost of it, as compared with the present so-called system, is insignificant, being anywhere from one-twelfth to one-quarter. For power, it has been proved that it can furnish it from 25% to 50%—anything up to 25 or 50-horse—for what a man can keep his own engineer and furnish his own fuel for, and the steam is always ready, night or day. The gas companies, horse railroads, and the property owners—some of them—are always found to be ready to fight any innovation on their 'rights'; yet we presume the people of Boston, as well as of many other cities, will sooner or later come to this common-sense way of doing business. Baltimore is already putting in these works, and estimates and specifications are made for two other cities which we are aware of, and we hope sooner or later to see the conservative men of Boston take the matter up and make a business of it."

TO TEST MILK FOR WATER.—A German chemist furnishes a very simple procedure for testing the amount of water in milk, which can be applied by anyone. All that is required is a small quantity of gypsum (plaster of Paris), say one ounce. This is mixed with the milk to a stiff paste, and then allowed to stand. With a milk of 1.030 specific gravity, and a temperature of 60° Fahr., it will harden in 10 hours; if 25% of water is present already, in two hours; if 50%, in one and a half hours; and with 75%, in 30 minutes. Skimmed milk which has been standing for 24 hours, and is of 1.033 specific gravity, sets in four hours; with 50% of water, in one hour; and with 75%, in 30 minutes. Heat should not be applied, as then the use of the thermometer would be required. This test is certainly very simple and not costly.

IMPORTANT TO FISHERMEN.—The *Scientific American* says it is a well-known fact that fish always return to the same ground each year to spawn, but that it has recently been discovered that they always follow the left-hand side of the river on their trips to the spawning grounds, and returning take the right-hand side of the river. Our fishermen should remember this.

STRUCK BY LIGHTNING WHILE UNDER WATER. At Halifax, N. S., May 29th, while divers were at work at Cole Harbor dike a storm came upon them, and the lightning striking an air pump passed down to a diver under the water. When brought up he was insensible, but his injuries are not serious.

GOOD HEALTH.

Climate in Consumption.

Apropos of the journey from Cannes to St. Petersburg of the invalid Empress of Russia, who went home in mid-winter for fear of dying away from her family, a distinguished Vienna physician publishes a vigorous protest against the practice of sending consumptive patients to warm climates without regard to the stage of their disease or their circumstances. He has taken note of 50 cases of such patients, who have been sent by their physicians to spend a winter in Italy or Egypt, and among them all he found only three who received any benefit from the change, while many were positively injured. Much that he says is applicable to this country as to Europe. No doubt many of our physicians prescribe a winter sojourn in Florida or Nassau, to patients in advanced stages of lung complaint, without much consideration of possible effects upon them of an enervating atmosphere, the absence of home faces and home comforts, and the weariness and loneliness of a listless life among strangers. A warm winter climate is no doubt beneficial in the early stages of the disease, and in some instances may effect a cure; and in more advanced stages its influence may alleviate the sufferings of the patient and retard the progress of the fatal malady. But the wise physician should carefully consider whether the possible benefits will not be more than counterbalanced by the fatigues of the journey and the discomforts and home-sickness attendant upon life in hotels, away from family and friends. Every one who has visited our Southern winter resorts, has been moved at the spectacle of melancholy invalids hoping for some magical effect from the climate, which they never should have been led to expect. Consumed with *ennui*, and no society save that of other patients, these poor people watch the thermometer and the progress of their ailments, shivering with cold when the mercury approaches the freezing point, and bitterly regretting the snug Northern homes which many of them should never have left.—*Materia Medica*.

SANITARY ERRORS.—It is a popular error to think that the more a man eats the fatter and stronger he will become. To believe that the more hours children study the faster they learn. To conclude that if exercise is good, the more violent the more good is done. To imagine that whatever remedy causes one to feel immediately better is good for the system, without regard to the ulterior effects.

WEEPING.—The physical, mental and moral effects of weeping are dependent entirely upon "circumstances," and these "circumstances" are very comprehensive, as they relate to the organization, temperament, education, association, business, etc., of the individual.

THE PHOSPHATES IN FOOD.—Prof. Horsford says, in a recent paper, it is a familiar fact that some persons of a feeble digestive power prefer embrowned meats and toasted bread, to undone flesh and plain bread. The difference between them is mainly due to the effects which incipient burning has produced; and one of these effects is the more or less perfect separation of the phosphates from the organic radicals entering into the composition of the tissue. The ashes of wheat, rye, oats, Indian corn and barley, and of seeds in general, contain phosphoric acid. It also occurs in the ashes of most animal tissues other than bones or teeth. In some of them, as in fish meat, the phosphates are feebly combined. A mere soaking of a piece of codfish in water for a few moments will separate sufficient phosphoric acid to yield a ready reaction with the usual tests. Fish as an article of diet has been commended, because of the facility with which it may be digested, and because it has been supposed to be especially suited to supply nutriment to cerebral tissue. It has been suggested that the facility with which the phosphates may be disengaged from the complementary part of the fish tissues, is the explanation of both these peculiarities, and is some degree of the process of digestion as a whole. The emulsion, which results from the action of the ferment and mineral acid, like hydrochloric acid in artificial digestion, is to produce an acid phosphate. It is but reasonable to infer that the addition of the acid phosphate to food, or its administration as a medicine, will prove nutritious.—*Medical and Surgical Reporter*.

A HOT TERM.—July is a trying month for children, in which disorders of the digestive system are prevalent, which, in cities, are always due to bad food and bad air, and improper clothing. It gives us pain to see how the poor people who throng the tenement houses in cities feed themselves and their children during these months. Wagon loads of cucumbers are distributed, potatoes which are very far from being ripe, young veal, stale meats of different kinds, and swill milk, or milk that has been doctored with stale starch and water, provoke disease and defy all the laws of health. All persons who work in the open air under a blazing sun should have a ventilated hat. Straw, chip, generally furnish a fair amount of ventilation without a special effort; still we fancy that there should be more ventilation than the common tightly-sewed straw hat affords. Holes may be made in the common felt hat so the breeze may pass through and keep the head cool. It is a good plan to keep a few green leaves or small twigs in the hat when exposed to the direct rays of the sun. After working and perspiring, warm clothing should be assumed, so as to keep up a gentle perspiration, growing less and less till the body has reached its normal condition.

DRINKING ICE WATER.—There is no more doubt that drinking ice water arrests digestion than there is that a refrigerator would arrest perspiration. It drives from the stomach its natural heat, suspends the flow of gastric juice and shocks and weakens the delicate organs with which it comes in contact. As a writer on human diseases says habitual ice water drinkers are usually very flabby about the region of the stomach. They complain that their food lies heavy on that patient organ. They taste their dinner for hours after it is bolted. They cultivate the use of stimulants to aid digestion. If they are intelligent they read upon food and what the physiologist has to say about it—how long it would take cabbage and pork and beef and potatoes and other meats and esculents to go through the process of assimilation. They roar at new bread, hot cakes and fried meat, imagining these to be the cause of their maladies. But the ice water goes down all the same, and finally friends are called in to take a farewell look at one whom a mysterious Providence has called to a clime where, as far as is known, ice water is not used. The number of immortal beings who go hence, to return, on account of an injudicious use of ice water, can hardly be estimated.—*Baltimore Sun*.

MEDICINAL PLANTS IN CALIFORNIA.—When the first Americans came to these shores they found that the Spanish and Mexicans were in the habit of depending largely, in case of sickness, upon simple extracts of native shrubs, herbs and roots. Some of the cures they performed bordered on the marvelous, and a knowledge of Yerba Santa, Yerba Langrado, Cascara Segrada, and a number of other medicinal plants, soon extended to the Americans, and found a place in the *Materia Medica* of civilized countries. The lists of leading druggists now contain regular quotations of several species, and shipments from this coast are increasing. The business, so far, is done by contract, Eastern firms, or parties on this coast, letting contracts to persons to furnish a given amount at a fixed price, there being as yet no sale in open market for these products. The price is, contractors say, very fluctuating. *Griodelia* robusta grows near the coast, in blackish macsee, and is not very plentiful; *Grindelia* squarrosa grows on the uplands and great valleys, where it is called tar-weed by some, and is troublesome in the fields. *Cascara Segrada* grows on hillsides and uplands in great thickets.—*California Horticulturist*.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Rich Gold-Bearing Deposit; Good News; Wagonman's Dry Gold Washer; Railroad Building in Mexico; California Copper; The International Exhibition of 1883, 17. The Week; Great Need of Penitentiary Reform; The Collision on the Sound, 24. Signal Service Weather Case; Circling the North Pole; Terrific Explosion of Gas; The Forestry Investigators, 25. Odd Fellows' Library Association; A Great Mine in Montana, 28.

ILLUSTRATIONS.—Wagonman's Dry Gold Washer, 17. A Weather Indicator, 25.

CORRESPONDENCE.—Ore Crushing.—No. 2, 24. Colorado County Notes, 28.

MISCELLANEOUS.—Causes of Anomalous Distribution of Rain on the Pacific Coast; The Tehuantepec Railroad; A Fossil Forest; Loss of Life by Lightning; A Ship Canal; Watts' Old Workshop; Zinc and its Uses; Our Future, 18. Utilization of Additional Species; A Mountain of Obsidian; Progress in Bodie District; Rich Quartz in Shasta; A Productive Mine; Growth of Our Manufactures, 22. Horticultural Exhibits at the Mechanics' Fair; Pacific Coast Money Order Offices; Change in Land Laws; A Grand World's Fair in New York, 26.

MECHANICAL PROGRESS.—The Sensitiveness and Isochronism in Governors; New Steam Boilers; Motive Powers of the Future; The New Steel Processes in the United States; To Keep Wagon Tires on the Wheel; Working Steel for Tools; Effect of Age on the Quality of Iron, 19.

SCIENTIFIC PROGRESS.—An Important Discovery; Progress in Utilization of Solar Heat; Sulphuric Acid as a Disinfectant; Atmospheric Polarization; Dr. Siemens' Newest Electrical Results; Force Exciting Electricity, 19.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Mortgages and Dividends, 20.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana and Utah, 20-21.

THE ENGINEER.—A Wonderful Little Steamer; Constructing and Driving Piles; Capt. Ead's Ship Canal; Economical Engineering in the St. Gotthard Tunnel, 23.

USEFUL INFORMATION.—Dynamite for Removing Stumps; Spontaneous Combustion; Dust Fires; How to Tell a Horse's Age; Heating Cities by Steam; To Test Milk for Water, 23.

GOOD HEALTH.—Climate in Consumption; The Phosphates in Foods; A Hot Term; Drinking Ice Water; Medicinal Plants in California, 23.

Dividend Notice.—Standard Con. M. Co.

The Week.

Since our last issue we have to note the continuance of seasonable and wholesome weather, which is especially favorable to farmers and orchardists. The apprehension which had been felt by some that the injury to the wheat crop was more general than had been reported, has fortunately been completely dispelled by the good news from the harvest fields, and there is now assurance of a fair yield of marketable wheat. The increased area will undoubtedly give an average crop of grain.

During the week the national holiday, which this year fell on Sunday, was celebrated in this city in a spirit of fine enthusiasm. The procession, of which the military was the conspicuous feature, was excellent. Beyond the inevitable fires—one of which near midnight was marked by serious injury to several firemen—nothing occurred to mar the festivity of the pleasant day.

No noteworthy incident has occurred on the Comstock since our last publication, though work continues to be carried on in a large and systematic manner. All the mining counties in this State continue their activity, and send encouraging reports of improvements and discoveries. The discovery of a deposit of remarkably rich gravel in Nevada county, an account of which is given in another column, will do much to promote prospecting and work in sections where gravel beds are supposed or known to occur.

Business in the city has been less active, owing to the fact that this is the vacation season, and business and professional men seek the sea-side, mountain and valley, for a few weeks' relaxation and recreation.

Great Need of Penitentiary Reform.

The shocking condition of the penitentiary system of California has been often exposed to the public attention by the press, and occasionally by some thoughtful philanthropist. It has been shown times and again that the utter lack of system and the entire want of discipline in our penitentiary had fatally perverted and defeated the objects of its institution. Thus far the matter has been unheeded. It would appear that not even the practical sense of the tax-payer had been aroused to the potent evil. That our citizens can sit apathetically in the presence of such a monstrous perversion of this clear intent of the penal institutions of the State is indeed remarkable. Sensible, hard-headed men, who directly pay the swelling taxes, do not apparently give the subject a random thought, or, if they do, are satisfied by indulging in a little querulous grumbling. This is a grave mistake, whether considered on the score of humanity or economy. It has been remarked that to spare deserved and just punishment is to encourage iniquity. There is small cause for wonder that our prisons are full to overflowing, and that there is a constant cry for more room and more cells, when the certainty that the punishment will be merely nominal, the restraint barely irksome, and the food and lodging substantial and comfortable, tempts the knave and the ruffian to risk the violation of the law.

How utterly had our penitentiary system is—a system which has been fitly characterized as a sort of "criminal university"—has been lately shown with painful clearness by no less an authority than a member of our judiciary. Judge Freelon, of the Superior Court, presided at the trial of the San Quentin murder case, in which both the slayer and the slain were convicts, and in the course of the trial the inner life of the prison was laid bare. Its enormities so impressed the Judge, who has been on the bench for years, that he deemed it to be his duty to give emphatic utterance to some of the thoughts which the history of the case suggested.

"Our State penitentiary does not," he remarks, "accomplish any one of the ends for which it is supposed prisons are built and maintained. First, it does not reform, or tend to reform. Just the contrary. The prison is a school of vice of every degree, the most debased and dangerous. There is a hierarchy of crime there, and the man who has committed, is committing, or plotting to commit, the most and the worst crimes, is the most admired and respected. The man who has some good instincts left is left out of fashionable prison society. The man or boy who gets there through some accident or misfortune soon learns that to be respectable is to be bad, and if he really be not bad by nature he must affect to be so. Again, this prison is no punishment for the professional criminal class. They are, as respects food, society, lodging, dress and amusement, much better off than they are hunting a living on the Barbary Coast. This is a little world of itself, has its own code of morals and manners, and the prisoners seem proud of the number of terms they have served." And such a flagitious system cannot be other than productive of evil. Judge Freelon concludes his terrible analysis by expressing the opinion that "the State should provide for a better classification of prisoners, for more enforced labor and more solitary confinement, so that even professional criminals would look at imprisonment as being some punishment, and consequently something tending to deter them from the commission of new crimes."

These are grave matters for the consideration of all good citizens—for the heads of families and the holders of property, and all the well-wishers of the State. The penitentiary at San Quentin is a standing menace to life and property; a perpetual danger to the young and inexperienced. It is doubtful if all the reeking slums of our cities produce criminals so rapidly and so fully equipped for vice as our State Penitentiary. But hitherto the glaring evils of the institution—than which the Sacramento Record-Union declares "no worse prison can be found probably on the earth"—have been exposed in vain. The supreme necessity for immediate and radical reform has been repeatedly made apparent; but it would appear that prison reform and prison discipline have come to be regarded in this State as sentimental absurdities. Other States have for years by intelligent legislation and faithful supervision, aided by private associations for promoting prison reform and discipline, sought to introduce the largest reform in their penal methods; and their efforts have achieved results that are cheering both to the humanitarian and the economist. They have shown that they could curb the vicious and induce some of them to reform; and that it was cheaper to do so than to permit the criminal class to grow in size and efficiency and to build costly prisons for their temporary withdrawal and accommodation. We cannot too soon or too faithfully act on the suggestion of Judge Freelon and make at least an attempt to establish a scientific system of classification and discipline for the government of our State penitentiary—a system that shall be at once certain and rigid and yet humane. Such a rigorous system, in which there should be no senseless cruelty, would constantly exercise a wholesome restraint and gradually lead to the reform now and then of a convict.

Ore Crushing.—No. 2.

[Written for the Press by J. RICHARDS.]

It is to be regretted that no careful experiments have been made and tabulated, as to this effect of different kinds of stamps on the various kinds of stone, so that constant performance could be fixed with some certainty. The results in different mills has, of course, been recorded, but the conditions vary in the different cases, and especially is there no fixed data as to the difference between wet and dry stamping.

The vastness of the mining interest both present and prospective on this coast warrants careful investigation in respect to pulverizing processes, because it is in this direction that invention seems most active; while, as pointed out in the previous article, the mechanism for pulverizing is no doubt the most perfect part of a modern plant.

The true object of search should be not for machinery to crush or pulverize faster, but to attain conditions which will permit the machinery now in use to work up to its full capacity.

There is no doubt that mineral stone of all kinds, whether hard or soft, is more friable and may be crushed at less expense when dry, yet the product of dry stamping is on an average one-third less than by the wet process. All experienced men will agree that this difference is not due to the stamp action, but to what may be called working conditions.

If some common quartz is placed in a chemist's mortar and pulverized for experiment, it will be found that up to a certain point the operation will be most rapid when the stone is dry. After this the conditions will change, pulverizing will become slow and difficult, but if water is added the effect will at once be increased, and the finishing process down to the fineness required will be comparatively easy. A stamp battery is only an enlarged mortar and pestles, and all facts thus far gathered point to a similar result in experiments made in quartz mills. All will agree that stone is more easily broken to a certain degree of fineness when dry; then the unfinished particles become enveloped in fine dust, which acts as an elastic cushion, absorbing the force of the stamps, and also preventing circulation, so the coarser particles may find their way beneath the stamps.

Improvement in manufacturing or mechanical operations of all kinds is derived from two sources, namely: inductive conclusions and experiment. The first suggests the latter, and if the two are properly combined they cannot fail to attain the best results. Experiment not guided by inference is an expensive and generally an uncertain course. Inference without experiment is still more uncertain. The two things must go together.

I propose to apply some inductive conclusions in these ore-stamping processes, and see if by that method the difference between the wet and dry operation are not fully borne out by the working conditions.

In the previous article reasons have been presented why the percussive, or stamp process, is better than any other. Leaving this, therefore, in so far as mechanism for pulverizing and treating of the conditions of stamp operation, we find certain requirements as follows:

1. Theremoval of particles from the stamps as soon as fine enough.
2. The separation of such particles from the coarser ones that require further treatment.
3. The removal of the finished pulp or sand from the battery.
4. Suspension so as to permit precipitation.

So far as crushing or pulverizing, these are what may be called the "ideal conditions," which, if perfectly attained, would permit the highest possible efficiency of stamps.

Beyond the batteries there are other requirements, that may be summarized as follows, for the common gold amalgamating processes: 1. The conveyance of pulp or sand for subsequent treatment. 2. Agitation to secure exposure of particles. 3. Maintaining mobility between particles, also to secure exposure. These have, however, to do only with mercurial extraction, and need not be considered in connection with pulverizing.

The purpose is to compare water in wet crushing with air in dry crushing, and determine as far as possible by inference how nearly the first named conditions or requirements can be filled in the two cases.

Before entering upon such a comparison it will be necessary to offer some explanation of the proposed method of employing air in dry crushing. Thus far it seems the application of air has only been in drawing off the dust from batteries—that is, removing what is in suspension, or thrown up by agitation and caught in weak currents.

There are insuperable difficulties in constructing air ducts and nozzles so as to catch the dust near to stamps; in fact, no such nozzle can be arranged so as to catch more than the flying dust, or what may be thrown into or near them by agitation. The strength of an induced air current in a battery is, theoretically, as the area of a plane through the battery compared to the area of the induction orifices, a difference too great for comparison, unless the volume of air passed through was so great that the expense for power and maintenance of pneumatic apparatus would more than equal any gain that could be expected in pulverizing. Fans and all kinds of pneumatic apparatus run heavily, and when moving on a low pressure are deceptive, generally consuming several times as much power as

is commonly supposed; hence, one of the first requirements in employing air as a separating and conveying medium is to have the pipes and nozzles small—only large enough to carry off freely the amount of material the stamps can prepare. It is probable that in all the experiments hitherto made, this principle has been lost sight of. The methods of collecting have rendered it necessary to employ large fans and larger quantities of air.

The crushing area of stamps rarely exceeds 50 inches. The operation is a concentrated one in this respect, and if this dust could be gathered at the point of crushing and a strong air current forced between the shoes and dies each time the stamps are raised, such a current could be small.

To secure this end there seems to be but one way, to draw the dust up through the top die or shoe by means of a central bore or duct of small diameter as possible.

In some plans now completed for a stamp mill, with dies 10 inches in diameter, the air aperture is made three inches in diameter. This, it is thought, will be ample, and perhaps in excess of what is required; at any rate, a current of air thus applied directly when the crushing is done, drawing to the center, may be quite small in comparison with what would be required if its course and action was not so complete.

The application of any effectual means for removing the dust in dry stamping, will, I believe, lead to important changes in the construction of batteries and stamps, and that the highest effect in dry crushing will be gained by heavier stamps falling a less distance and having a positive rotation, the latter not in a degree, nor in a manner to cause extra abrasive wear, but with such limit as to time as might be spared. One-third of a revolution, or perhaps less, while the stamps run down, would be enough. The effect of such rotation would of course be dependent upon the weight of the stamps. There is no gain, or, at least, but little, in the rotation of stamps within what may be called a crushing height, and I strongly incline to the opinion that the rotation of ordinary stamps by the cam motion, while it serves important mechanical ends, has but little to do with the working effect.

In the case of stamps having a positive rotation, as in the "Kendal machines," there is no doubt that the removal of the "neutral axis" in the dies will improve their action, so the central bore for air would be no objection. The same may be said of the strength of dies and shoes, especially if made of molded steel. A central bore would greatly increase their strength and insure greater homogeneity, which at present is the main difficulty in preparing them.

THE COLLISION ON THE SOUND.—One of the theories of the cause of the fatal collision of the steamers *Narragansett* and *Stonington* on Long Island sound recently, is that the meaning of one of the prescribed signals was misunderstood. The provision of law is that when two vessels are approaching each other each shall pass to the right, giving as a signal that they will take that course one blast of the whistle; and if, for any cause, either shall desire to pass to the left, it must signal by two short blasts in quick succession. The inspectors have received information that the *Narragansett*, when in the fog at the time of the disaster, blew her whistle continuously at intervals of half a minute, and that this prescribed fog signal was mistaken by the *Stonington* to mean that the *Narragansett*, which could not be seen at the time, meant to her left. If these statements are true they will explain in part the cause of the fatal blunder. Referring to this disaster, the New York *Mail* makes these pertinent suggestions: "The crash of the *Stonington* and *Narragansett* was followed by an outburst of flames which forced the bewildered passengers into the water almost without time to secure life-preservers. Had there been no fire the passengers could have been removed in the life-boats and there might have been no loss of life. The fire was caused by gas. Is gas a safe illuminator for passenger vessels? That question is worth consideration by travelers and by owners of steamboats. Let the latter inquire whether it is not possible to adopt a generator which will both furnish their vessels with electric headlights, and illuminate the cabins with a light which will be perfectly safe."

CALIFORNIA MEAT PRODUCTS.—All meat producers will be glad to hear of steps of progress in the introduction of our meat products into new channels of consumption. The *Commercial Herald* has the following item of trade news: The Russian government has just concluded a contract with Merry, Faulk & Co., of this city, for a round lot of beef, say, 2,250 hbls. or 450,000 lbs. of mess beef, which is the largest contract of the kind ever made on this coast. The meat, barrels and salt used in filling the contract are all of California production. A sale is also reported by the same parties, for U. S. Army supplies, of 50 hbls. mess pork at \$20.25 per hbl., and 15,000 lbs. extra clear bacon, in cases of 200 lbs. each, at \$11.60 per cwt. This is certainly a pleasant feature. For years we have maintained that we could supply the Government with beef and pork of better quality and upon more advantageous terms than it could be purchased for at the East, and sent to this coast via Cape Horn. The percentage of loss by sea through the tropics is always large, and now by experience it is found that our own Government, as well as that of Russia, find it for their interest to purchase their meats in California.

Signal Service Weather Case.

The extension of the U. S. Signal Service has proved of great value to all our outdoor industries. The great trouble in bringing its results to bear upon agriculture has been the difficulty of making known forecasts, etc., to those remote from the cities or large towns. Gen. Myer, Chief of the Service, now has it in mind to issue a compact arrangement of meteorological devices so that those distant from centers of information may have some means for arriving at better judgments of coming weather than they now have. Of course it is not pretended that any device will give infallible forecasts, but this design is to bring the best modern means of judging within the reach of all, that the benefits of the government service may be widely disseminated.

Our engraving on this page represents the "weather case or farmers' weather indicator," which will be set up so long in rural postoffices throughout the country. The case is 31 inches high, 13½ inches wide and 4½ inches thick. The front is covered with a glass door, which is kept closed except when making observations and adjusting the different instruments. The engraving, which of course presents the weather case in miniature, is worthy of careful study and a leisure hour will be required to arrive at a full understanding of its plan and details. We shall give as full a description of the different parts and their uses as we have space for at this time, as we deem this subject one of general importance. We understand that the cases are not for sale, but are to be erected here and there at government expense for the public benefit.

The pointer or index at the top of the case (No. 1) slides on the brass arc; it is known as the "sunset barometer index," and indicates, when set, by the figures to which it points on this "main barometer scale," which is just below it, the reading of the barometer at the time of the sunset yesterday. The "main barometer scale" (No. 2) exhibits all the barometric readings likely to be used with this instrument. The pointer (No. 3) just below the "main barometer scale" is called the "reference index," and indicates by the figures to which it points on the main barometer scale, when the instrument is set, the mean or average reading of the barometer at the place at which the instrument is set and for each separate month. When the barometer reads above or below this reading at any place, such reading is said to be "above the mean" or "below the mean" for that place in that month. This reference index is established in the exact central line of the face of the case. The long brass hand over the glass face of the barometer is known as the "long pointer," and indicates, by the figures of the "main barometer scale" to which it points when set, the reading of the barometer when last set. The black pointer on the face of the barometer under the glass face is known as the "short pointer," and indicates the existing pressure of the atmosphere at any time the instrument may be examined.

There are for each place and each month two kinds of winds: First—Winds which, blowing from certain directions, are at that place and in that month more likely than other winds to be followed by rain. These are called "rain winds." Second—Winds which, blowing from certain directions, are at that place and in that month less likely than other winds to be followed by rain. These are called "dry winds." The wind direction for any day or time must be seen and taken at each place or station by a vane as well located as practicable. The "wind disk" (No. 8) consists of a brass circle, on which slide freely two arcs—a red arc, called the "dry wind arc" (No. 9), and a blue arc, called the "rain wind arc" (No. 11). In the center of the disk is a pointer turning with a turning-screw, and called the "wind disk pointer" (No. 10). Around the disk are letters to show directions, as N. for north, E. for east, NE. for northeast, etc.

The pointer and scale (No. 5) on the right of and below the barometer are called the dry-wind time record, and the pointer (No. 7) is called the "record pointer," and indicates, when set, the length of time the wind has been blowing continuously from a "dry" direction, by the figures showing the number of hours on the scale to which it points.

The pointer and scale (No. 4) on the left of and below the barometer are called the rain-wind time record, and the record pointer (No. 6) indicates, when set, the length of time the wind has been blowing continuously from a "rain" direction, by the figures showing the number of hours on the scale to which it points.

The record pointer on the rain-wind time record (No. 6) is always turned by the thumb-screw, and set pointing at the figure 0 on the scale when the wind is not blowing in the rain-wind direction. In the same way the "record pointer" on the dry-wind time record (No. 7) is always set pointing at the figure 0 when the wind is not blowing in the dry direction.

The sunset disk (No. 12) consists of a circular disk one-half of which is colored red and one-half of which is colored blue. The disk turns upon a central turning screw in such a manner that half of the disk shows through a semi-circular opening in the face of the weather case. The sunset disk is set as follows: At the exact time of every sunset the western sky and the character of the sunset is carefully observed. The examination ought to be minute and careful, lasting for about fifteen minutes. If the sunset sky is clear or red, or markedly what is known as a "fair weather sunset"—a sunset

such as is generally held to indicate a clear or fair day to follow on the next day—a day on which it will not rain—the sunset disk is turned by the turning screw until the semi-circular opening shows all red. The sunset disk, thus turned, is described as set for a "fair weather sunset."

If the sunset sky (the western) is cloudy or foul, or markedly what is known as a "foul weather sunset," a sunset such as is generally held to indicate foul weather to follow on the next day—a day on which it will rain—the sunset disk is turned by the turning screw until the semi-circular opening shows all blue. The sunset disk thus turned is described as set for a "foul weather sunset." If the appearance of the western sky and the character of the sunset are neither markedly those of a "fair weather sunset" or of a "foul weather sunset," but such as to leave the observer in doubt how to style it, the sunset disk is turned to show half red and half blue, or "doubtful." The sunset disk,

slides on the brass slide (No. 16). In the center of the case is the "dry and wet bulb scale," marked on the paper on which is the central brass slide bar (No. 19), and on this slide move the dry bulb keeper (No. 17) and the wet bulb keeper (No. 18). To set the thermometers examine first the dry bulb thermometer and move the "dry bulb pointer" (No. 15) on the slide until the outside point is exactly level with the top of the mercury in the thermometer—as near to it as practicable. Examine next the wet bulb thermometer, and move the wet bulb pointer (No. 16) on the slide until the outside pointer is exactly level with the top of the mercury in the wet bulb thermometer, or as near to it as practicable, then turn the dry and wet bulb scale, and on the "central brass slide bar" (No. 19) move one of the keepers until it touches as nearly as possible—is on an exact level with the inside pointer of the "dry bulb pointer," then move the other keeper until it touches, as nearly as practicable—is on an

A WEATHER INDICATOR.

thus set, is described as set for a "doubtful weather sunset."

In the lower part of the weather case there are two thermometers, a dry bulb thermometer (No. 13) on the left hand side of the case, and a wet bulb thermometer (No. 14) on the right hand side. The dry bulb thermometer is like any other thermometer, and shows by its readings the temperature of the air. The wet bulb thermometer is one, the bulb of which is kept constantly moist by the water passing up from the glass reservoir, through the wicking which covers the thermometer bulb. The readings of the dry bulb thermometer and those of the wet bulb thermometer are more and more unlike, or farther and farther "apart," as it is called, in proportion as the air contains less and less moisture, that is, is becoming drier. The readings of the dry bulb thermometer and those of the wet bulb thermometer become more and more alike—are nearer and nearer together—in proportion as the air contains more and more moisture. That is, is becoming saturated or wet.

By the side of the dry bulb thermometer (No. 13) is the dry bulb pointer which slides on the brass slide (No. 15). By the side of the wet bulb thermometer is the wet bulb pointer which

exact level with the inside pointer of the "wet bulb pointer." The thermometers are now set and the difference between their readings can be known by counting on the "dry and wet bulb scale" the number of degrees between the keepers.

When the thermometers are examined and set again, following the same plan, it will be easily seen whether the "keepers" are, when set, farther apart than they were at the previous setting, or whether they are, when set, nearer together than at the previous setting.

If they are further apart, the thermometers are said to be "separating"; if they are nearer together, the thermometers are said to be "approaching." Other things being equal, the thermometers show, when they are "separating," that the air is becoming more dry, one sign of approaching fair weather. The thermometers show, when they are "approaching," that the air is becoming more moist or damp, one sign of approaching rain.

The weather case is not intended to be used independently of the official weather reports. It is to be used always in connection with them. The weather case is for the purpose of supplementing the official reports by showing the local instrumental indications and giving other

information. It is intended especially for use at farmers' postoffices and places reached with difficulty by the printed reports. It will supplement often whatever knowledge there be of local signs, with the indications of the instrument. Its careful use, taken either with the furnished reports or even without them (if they chance to fail) will often enable the character of the coming weather on the coming day to be so judged as to determine what kind of work or undertaking it is wise to plan for or to omit. The case gives the local instrumental indications, and will frequently aid in making fair forecasts for the next day.

CIRCLING THE NORTH POLE.—Lieut. Weyprecht's proposition for a circle of observing stations around the north pole region, is about to be practically carried out, says *Nature*. The Danish government has resolved to establish a station at Upernivik, in west Greenland; the Russian government has granted a subsidy for an observatory at the mouth of the Lena, and another on the new Siberian islands; Count Wilczek will defray the expenses of a station on Nova Zembla under the direction of Lieut. Weyprecht; the U. S. Signal Service Bureau, under Gen. Myer, has received permission to plant an observatory at Point Barrow, in Alaska; and it is expected that Canada will have a similar establishment on some point of her Arctic coast. At the Hamburg Conference it was announced that Holland would furnish the funds for a station in Spitzbergen; and it is expected that Norway will have an observing post on the extremity of the Provinces of Finnmark. This is a good beginning, and it is hoped that some sort of agreement will be established to have all the observations made after a uniform method, otherwise their value will be greatly decreased.

TERRIFIC EXPLOSION OF GAS.—In London, on the evening of the 6th inst., a terrific explosion of gas occurred in the vicinity of Tottenham Court road. For a long time it had been noticed that there was a large and constant escape of gas, and finally a workman was sent to examine the pipes. He applied a light to the point where pipes joined, and immediately there was a series of explosions, at least six, each causing a deep trench from 3 to 10 yards long. From one of these trenches 16 persons were extricated. Two persons were killed, two fatally wounded and some 30 more or less injured. One house was demolished and over 400 injured. Along the line of the explosion all the window glass was broken and the chimney pots thrown down. Dense volumes of gas issued from the trenches, and the air was suffocating. Buildings and streets in the neighborhood were enveloped in total darkness. An eye-witness says that at the moment of the explosion he noticed a mass of bricks and stones shoot up about 100 ft., followed by a loud report which rolled down the street like artillery fire. The workman who applied the light in search of the leak was blown a great distance and killed.

THE FORESTRY INVESTIGATORS.—We have had the pleasure of meeting Prof. C. S. Sargent, of Harvard University, and Drs. Engelmann and Parry, his associates, who are now on our coast in pursuit of knowledge concerning our forest resources and lumbering interest, for use in the census reports of 1880. We have made several allusions to the special work in which these able botanists are engaged. They will betake themselves at once to the forests of the north coast, and on their return will make special studies of California and Arizona forests and influences affecting them. We trust they may be speeded in their work by all our people with whom they may come in contact. Great interest will await the reports of their investigations, which will come ere long, and form one of the most valuable features of what promises to be the best census ever taken in this country.

CALIFORNIA TREE IN AUSTRALIA.—An article in the Melbourne *Times* gives notes of the growth of a California tree in the Melbourne botanic garden. We read that a fine specimen of our redwood may be seen towering up far above the roof of the hush sheds in the propagating department. This specimen is about 55 ft. in height, the circumference of stem at the base being 7 ft. 5 in. It has made rapid growth during the past four or five years, and is supposed to have been planted by Mr. John Dal-lachy when curator of the gardens, some 25 years ago.

AT THE GEYSERS.—From a party that visited the Geysers from Anderson Springs we learn that 160 persons were there on the Fourth, the largest collection of visitors ever known there. A large number of bathers and spectators were at the warm swimming baths in the forenoon. The road from Anderson Springs to the Geysers, some nine miles, is a wild and picturesque route.

HANDBOOK FOR MICROSCOPISTS.—We have received from the Industrial Publication Co., New York, a copy of the Microscopists' Annual for 1879. This useful little handbook contains tables, rules and memoranda; a list of microscopical societies and their officers; and a directory of the principal makers, dealers and importers of microscopes in Europe and America; and is apparently indispensable to all who have occasion to use the microscope.

Horticultural Exhibits at the Mechanics' Fair.

The managers of the fifteenth industrial exhibition of the Mechanics' Institute have placed the Horticultural Department of the exhibition under the charge of the California State Horticultural Society. At the meeting of June 25th the Horticultural Society formally accepted the trust and unanimously adopted a resolution, pledging the members to earnest efforts to make the exhibition worthy of our State, and, so far as possible, representative of our grand horticultural interests.

The society invites every plant and fruit grower in the State to prepare at once to transmit the best specimens of flowering and foliage plants and fruits for exhibition at the fair, which will open in the spacious pavilion of the Mechanics' Institute, in this city, August 10th, and continue for five weeks.

The competition for the liberal premiums will be offered to growers only, and each producer is invited to compete, whether it be for a single award or for several. The aim of the society is to draw out the very best that the State can produce in the articles named. The popular interest is now turning strongly toward development of our horticultural resources, and all exhibitors of choice growths will not only do themselves credit, but will make known the possibilities of their regions, and of the State in general.

The exhibition will be wholly in charge of the Horticultural Society, and the appointment of judges will be made with reference to their especial fitness for examination of exhibits entrusted to them. The premiums will be awarded by the Mechanics' Institute upon the recommendation of the society's committees. The greatest care will be taken in the arrangement of specimens, that their excellence may be recognized.

All professional and amateur horticulturists in the State are invited to do what they can to make this year's exhibit comprehensive and representative. Great care should be taken in selecting, plucking, wrapping and packing choice specimens, and all varieties must be correctly named. As the fair will be open for five weeks, each sample should be sent just as it approaches its best estate, and thus all varieties may be shown in their prime and all parts of the State, both early and late, can be represented by the fruits which mature during the progress of the fair.

Special attention will be given to the proper display of new fruits, both California seedlings or those lately secured by importation, so that the progress made in these directions may be generally understood.

All exhibits should be shipped to "Horticultural Exhibit," Mechanics' Fair, San Francisco, Cal. All intending exhibitors are requested to announce at once what exhibits they expect to make to the Secretary, E. J. Wickson, 414 Clay street, San Francisco.

PACIFIC COAST MONEY ORDER OFFICES.—The following postoffices on this coast will be made money-order offices after the first Monday of next August, provided the respective postmasters furnish the necessary additional bonds: California—West Berkeley, Alameda Co.; San Mateo, San Mateo Co.; Calistoga, Napa Co.; Tomales, Marin Co.; Lompoc, Santa Barbara Co.; Aden, Modoc Co.; Willows and Arhuckle, Colusa Co.; Redding, Shasta Co.; Fort Jones, Siskiyou Co.; Loyalton, Sierra Co.; Boca, Nevada Co.; Orange, Los Angeles Co.; Turlock, Stanislaus Co. Nevada—Camp Halleck, Elko Co. Oregon—North Yamhill and Dayton, Yamhill Co.; East Portland, Multnomah Co.; Centerville, Umatilla Co.; Hillsboro, Washington Co.; Independence, Polk Co. Washington Territory—Spokane Falls, Stevens Co.; Golden Dale, Klukitak Co.

CALIFORNIA LAND DECISION.—The Commissioner of the General Land Office rendered a decision, June 24th, in the case of the Rancho San Jacinto Nuevo, in San Diego county, rejecting the Thompson survey of 1876, and instructing the Surveyor-General to make a new survey, to comprise 11 square leagues, or about 49,000 acres, within the exterior boundaries. The preliminary survey has been approved, and a patent will shortly be issued by the General Office for the Rancho Los Palas Verdas, comprising 12,000 acres, in Los Angeles county, confirmed to Juan Sepulveda and Jose Loreto.

In the Head Center mine, Tombstone, the ledge has been tapped at the 300 level, which shows rich in face gold and horn silver. In Contention the ledge has been cut at the 312 level, with good ore also running northeast. On the 162 level a rich body of chloride has been struck.

The Gold Stripe mine in Plumas county, Cal., is again producing ore in sufficient quantity to justify the starting of the 24-stamp mill, which was set in operation a few weeks ago. It is said that a new body of ore has been discovered.

Change in Land Laws.

The new regulations set forth in the following letter from the General Land Office at Washington, are now in force.

To District Land Offices—GENTLEMEN:—Appended hereto is a copy of the act approved May 14, 1880, which changes existing laws and regulations relative to the entry of certain classes of land:

SEC. 1. That when a pre-emption, homestead or timber culture claimant shall file a written relinquishment of his claim in the local land office, the land covered by such claim shall be held as open to settlement and entry without further action on the part of the Commissioner of the General Land Office.

This will be held to apply only to the relinquishments which are filed subsequent to date of said act, viz: May 14, 1880.

You are instructed not to accept or act upon any relinquishment, unless made before you, which has been duly subscribed by the claimant on the back of his duplicate receipt, acknowledged, witnessed and executed in a manner which under the laws of the State or Territory in which the land is situated would be sufficient as a valid transfer of real estate. In case of the loss of a duplicate receipt or declaratory statement, an affidavit of such loss must accompany the written relinquishment.

Immediately upon a relinquishment duly executed as above, being received at your office, you will proceed as follows:

1. The Register will note on the relinquishment over his signature, the day and hour of its receipt by you.

2. Write the words "cancelled by relinquishment" (giving date), opposite the record of the entry in the tract book, the register of entries and the register of receipts.

3. Draw a line over the numbers of the entry on the township plat.

4. On Monday of each week you are directed to transmit to this office all the relinquishments which have been accepted by you during the preceding week.

When the relinquishment shall have been received and noted as above, you will hold the land embraced in the relinquished entry as subject to settlement or entry by the first legal claimant; the intention of said section, as understood by me, being only to prevent the delay resulting heretofore from awaiting action on such relinquishment by this office.

SEC. 2 is designed to secure to the contestant therein named, for the period of 30 days from notice of the cancellation of a prior entry of the character specified, a preference right to initiate his claim to the same land. It is not intended to grant such contestants the unconditional right to final entry, as I construe the section as preceding settlement or entry by any other party during the period named.

SEC. 3 places homestead settlers on unsurveyed public lands on the same footing with pre-emption settlers under existing laws. This section protects the claim of an actual settler upon unsurveyed land, provided he shall make homestead entry of the land within three months from the filing of the township plat of survey in the district land office, the same as the pre-emptor is now protected by filing his declaratory statement within the same period, and if the homestead settler shall fully comply with the law as to continuous residence and cultivation his statement defeats all claims intervening between its date and the date of filing his homestead application. In making final proof his five years' residence and cultivation will commence from date of actual settlement.—C. W. HOLCOMB, Acting Commissioner.

A Grand World's Fair in New York.

For two years a constant agitation has been kept up in New York for the holding of an international exhibition in this country in 1883. The dwellers in towns remote have, during this period, heard but little of the labors of the handful of public-spirited men who have persistently carried forward the movement to the point it has now reached. Patiently and prudently they have gone on from stage to stage, having the satisfaction at each successive step to witness a decided advance in all the essential elements of success. The holding of an international exhibition in this country in 1883 is now an assured fact. The initiatory difficulties inseparably connected with a scheme of such magnitude, particularly those in regard to the obtaining of necessary legislation, have all been overcome, and the preliminary arrangements and complete organization of the United States International Exhibition Commission of 1883 are being pushed forward to a speedy completion. A special act of Congress providing for the holding of such exhibition has been obtained; bills have been passed in the New York Legislature granting to the Commissioners who may be appointed powers to acquire such lands, etc., as may be requisite, and the Governors of the several States are rapidly nominating Commissioners to assist the project to a successful termination. The plan of the proposed exposition is on a scale of such magnitude that it completely eclipses everything of the kind in the past, and may probably never be surpassed in the future, and the movement has now entered upon a career of popular recognition and public favor which guarantee the ultimate accomplishment of all its projectors have hoped to realize.

Business Directory.

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.
It is with pleasure that we publish the following from prominent Architects in this city:
Believing that a journal of this kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Huern, John Marquis, B. McDougal & Son, Wm. Mosser, Wm. Curlett, Meeker & Banks, W. C. Hoagland, S. & J. Newsom, B. Hendrickson.

OXYGEN.

What is it? Everybody knows it is as essential to life as food itself. Yet when people are ill for the very want of revitalization through respiration, they dose themselves with drugs and bitters to the effect of demoralization! All Invalids should read Drs. STARKEY & PALEN'S (Phila.) Treatise on Oxygen, which is sent free to all who may ask for it. The subject is worthy of investigation. References to physicians in San Francisco, who use and prescribe Compound Oxygen in practice. As prepared for home use (conveniently sent to any address) it may be obtained of H. E. MATHEWS, 606 Montgomery Street, S. F., upon the same terms as furnished by Drs. Starkey & Palen, Philadelphia, Penn. Complete instructions with each package.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1859.
This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore. It contains 126 pages, embracing illustrations of furnaces, implements and working apparatus.
It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.
Price, \$3.00 cloth, postage free.

John Olsson, Model Maker.

Models for the Patent Office, in Wood or Metal. Separate rooms for inventors to perfect their inventions. Chemical Apparatus. Pressing and Stamping of all kinds of Metals.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto, 224 Illustrations.

By ROBERT GRIMSHAW, Ph.D., M.E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, ash, Malay, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, seasoning, gumming, filling, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 96 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, 100 pages, 10 illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

March 10 1880.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated, 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Post-paid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Post-paid, \$1.00. Sold by Dewey & Co., S. F.

A New Edition.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. 1880. A valuable and carefully written work. Postpaid, \$3.00. Sold by Dewey & Co., S. F.

TO MECHANICS—FOR SALE.

The Globe Iron Works,

FOUNDRY and MACHINE SHOP.

Cor. Main and Commerce Streets, near Steamboat Landing, STOCKTON, CAL.

For particulars apply to JOHN CAINE, Proprietor.

The Explorers' and Assayers' Companion,

(Third edition.) Price of Vol. 1, \$6.

Forwarded (post-paid) from the MINING AND SCIENTIFIC PRESS Office, by DEWEY & CO.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING JUNE 20TH, 1880.

229,383.—GUN-LOCK—W. N. Crabtree, Porterville, Cal.
229,387.—ORE CRUSHER—J. T. Davis, S. F.
229,463.—AIR COMPRESSOR—H. Richman, S. F.
229,500.—DESULPHURIZING ORES—H. F. Williams, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions* rendered upon patent cases in litigation, for the benefit of our readers:

DECISIONS OF THE U. S. COURTS.

Williams vs. Rome, Watertown and Ogdensburg R. R. Co.

U. S. Circuit Court, Northern District of New York.—Decided April 21, 1880; Blatchford, J.

In a suit in equity the plaintiff on recovery for infringement may obtain the profits to be accounted for by the defendant in addition to the damages which the plaintiff has sustained by the infringement, and these profits incident to a decree in equity cannot be turned into the plaintiff's pocket, which would have been the remuneration in a suit at law.

A decree entered for the plaintiff for \$3,545.96 as gains, profits and advantages, with cost.

Strauss et al. vs. King et al.

U. S. Circuit Court, Southern District of New York.—Decided April 29, 1880; Blatchford, J.

The application of rivets to pockets for uniting and closing the end of the seam at the corners, as claimed in reissued patent No. 6,335, dated March 16, 1875, involves invention, is not a mere double use or aggregation, and is patentable.

This case has been contested with great vigor. The bill was filed in Nov., 1876. Testimony was taken from May, 1877, to July, 1878. The plaintiffs examined 283 witnesses, and the defendants 145. The plaintiffs' proofs cover 2,465 printed pages, and the defendants' 1,196. The plaintiffs' brief covers 323 printed pages, and the defendants' 152. Infringement is not contested, but the defendants rely on want of patentability and want of novelty in the thing patented.

The usual decree for the plaintiffs.

Spill vs. The Celluloid Manufacturing Co.

U. S. Circuit Court, Southern District of New York.—Decided May 25, 1880; Blatchford, J.

1. The invention of the pretense as prescribed consisted in the use of camphor and alcohol in about equal proportions as a solvent of xylidine. The defendant mixed ground and dried xylidine with pulverized dry camphor, and then immersed the mixture in alcohol until the xylidine was dissolved: Held that it is immaterial, so far as the invention and the claim of the patent are concerned, whether the camphor and alcohol are mixed so as to dissolve the camphor in the alcohol and then the xylidine is put into the solution, or whether either the alcohol or the camphor is first mixed with the xylidine and then the third substance is added.

2. The invention, patent Nov. 30, 1869, No. 97,454, embraces the bringing together of camphor, alcohol and xylidine, causing xylidine to be dissolved or softened, so as to be more easy of conversion or working into compounds or articles containing xylidine.

3. In Spill's patent, No. 101,175, Mar. 22, 1870, the real invention covered is to be regarded as the bleaching of xylidine by ordinary bleaching agents directly after the converting acid had been washed out of it and before anything had been mixed with it which might interfere with the action of the bleaching agents.

U. S. Stamping Co. vs. King et al.

U. S. Circuit Court, Southern District of New York.—Decided June 1, 1880; Blatchford, J.

1. Letters patent, No. 119,705, granted E. A. Heath, Oct. 10, 1871, for an improvement in cuspadors, constructed and sustained.

2. Where the invention embraced by a prior patent is held not to anticipate a later patent upon which suit is brought, a reissue of such prior patent granted after the date of the later patent can have no effect upon the same.

3. A reissued patent has the same effect and operation in law as though it had been originally filed in the corrected form only on the trial of actions brought on it for causes thereafter arising, and has no such effect in any other cause or on any other purpose.

4. A preliminary injunction will not be refused, by reason of the fact that on a suit brought by the former owners of a patent it was declared invalid, where it also appears that it has been repeatedly sustained in other suits, and that there is important additional testimony which was not before the court rendering the adverse decision.

* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

ADVANTAGE OF THE RAILROAD.—The Reese

River Reveille, Austin, Nev., bears cheerful testimony to the advantages which are already felt in that section through the operation of the Nevada Central R. R., which connects Austin with the great transcontinental line. That paper says the business of the road is steadily increasing, and that the amount of freight passing over it is greatly in excess of what was anticipated; and it is believed that the railway will prove a valuable investment to the owners. Already a number of outside mining properties have become active on the promise of cheaper and quicker transportation, and others will follow the example during the summer. Business is increasing through Reese River valley, and south of Austin especially the mining districts have grown in importance since the completion of the Nevada Central.

At Anderson Springs the Fourth was very sociably but quietly observed. A picnic dinner was given by Mrs. Anderson and her daughters in the grove surrounding the hotel. Some 75 persons partook of the bountiful repast enchantingly spread amid delightful surroundings. A few campers and neighbors were among the invited guests. The hostess (nearly 70 years of age and one of the sprightliest of the party) was well toasted for the patriotic and kind-hearted spirit shown.

El Dorado County Notes.

EDITORS PRESS:—A few notes from the El Dorado county mines may be interesting to the readers of the PRESS. I have been in the county only a few days, and so have visited but few mines as yet, but I have already seen enough to convince me of what I, with many others, have long suspected to be a fact, viz: that one of the most suicidal and fatal mistakes made by the people of San Francisco and California is entertainment of the erroneous idea that the California gold fields are, to use a common phrase, "played out," and to obtain the precious metals in profusion it is necessary to go to the Comstock or to Arizona. A combination of causes has brought about this state of things, the most powerful and effective one being, probably, that the rich mining belt of California is not sufficiently remote from Pine Street and Pauper alley, in San Francisco, to prevent those who are swindled out of their spare change in and about these localities to pay flying visits to the mines, and see for themselves whether the statements made on paper and transferred from the hands of one street operator to another until it finds its way into the one general coffer of the bonanza kings, are truthful and reliable accounts of the amount of the auriferous substances actually extracted, or to be extracted.

The further from San Francisco you locate a new strike, the easier you induce capitalists and those looking for mining property to invest. There are mines right here in El Dorado county which their owners could not dispose of for \$10,000, but which, if they could be transferred to the remote wastes of treeless, waterless regions of central Nevada or some other distant locality, would be worth a round million, and could be sold for it, too. It is a fact that the "outside barbarian" has no idea of the wealth of gold which is stored away in these California hills, of easy access to the industrious miner. And this leads me to state that industrious miners are scarce in California. This country is full of old human fossils, relics of the earlier days, when the precious metal could be washed from the gravely ravines of California with a pan in almost fabulous abundance. This process is the only one known to many of these old timers, and they do not care, in their inertness and indifference, to learn of any way to extract the exhaustless store hidden away in the darksome caverns of the earth. This being the case, and the bonanza kings and rings diverting the attention of capital away from California, has resulted sadly for this rich auriferous region. But a slow but certain change is taking place. The depression of the Comstock and other stocks handled in San Francisco, and the activity and energy of a few enterprising capitalists who had the sagacity to discern the truth concerning the undeveloped wealth of California, is beginning to effect a reform in favor of this region, and I predict that in the near future capital will seek and find profitable investment in California mines.

I have visited the Gold Hill district, on the south side of the river. Here one of the most interesting mines is that owned by Kimball & Audlin, named the Mountain View mine. Over a year ago this mine was discovered, and although no mention of it has ever been made in the newspapers, you can form an idea of its richness when I state that Mr. Kimball, soon after its discovery, pounded out with a hand-mortar in one day \$3,000. Don't imagine, either, that the Mountain View mine is a "pocket" mine. The lead has been followed and opened up for only 150 ft., and the croppings all the way show rich rock. I was shown a 2½ ounce piece of rock which weighs \$38. A 11 pound piece was crushed with a hand-mortar, and \$800 was taken out. There are many such mines in El Dorado county. The Esperanza, in the Garden Valley district, owned by Messrs. Burlingham & Alderman, is another very rich mine. I went through this mine myself. The ledge near the surface is two ft., widening rapidly in the descent. At the depth of 30 ft. the ledge is 7 ft.; at the end of the 100-ft. tunnel it is 29 ft., and at 42 ft. below the tunnel widens to 31 ft., showing the interminable extent of the lead. A mill will soon be erected on this mine. This firm is also erecting a mill on the "Old Judge" mine, another rich mine, in the Kelsey district. But I will tell you mors of mines and mining in El Dorado county in my next. A. J. B.

LAND CASE DECISION.—A dispatch from Washington says that in the case of the pueblo lands of San Jose the Acting Commissioner of the General Land Office has decided that the small tract of land known as "Willow Grove," at the head of Guadalupa river, must be included in the official survey. This tract of land is owned by the Odd Fellows' Savings Bank of this city, and has been greatly improved by that corporation, which holds its title under the Pueblo Grant.

A PRODUCTIVE MINING DISTRICT.—The total production of bullion in the district of Silver Reef, Utah, says the Salt Lake Tribune, since the opening of the mines up to July 1st, is \$3,261,054. Considering the fact that this silver bullion was produced from sandstone which many of the world's experts had declared never contained metal, the production of Silver Reef is certainly remarkable.

ODD FELLOWS' LIBRARY ASSOCIATION.—We

have received from Mr. Geo. A. Carnes, librarian, the 25th annual report of this association for 1879-80. The report shows a very creditable condition of affairs. The receipts for the year were \$10,549.99, and the disbursements \$8,673.26, of which sum \$2,693.89 were paid for books, newspapers and magazines, and for binding and repairing books. The number of volumes on the register is 36,777. During the year donations of 425 volumes were made to the House of Correction and 189 to the State Prison at San Quentin. The number of volumes lent during the year was 96,567, classified as follows: belles lettres, 2,736; biography and letters, 3,054; history, 2,798; novels, 76,819; periodicals, 2,711; poetry and drama, 2,235; sciences and art, 2,074; theology, 365; voyages and travels, 3,145. It will be observed that the tastes of the ordinary reader, who has not yet learned to select "books which are books," tends towards the novel, but Mr. Carnes says it is his ambition to bring the circulation of the novel within the limits of the rule in the so-called "intelligent" communities of the Eastern States, beyond which his association is now some 8% or 10% in excess. The Librarian utters a mild but very reasonable complaint against the general practice of marring and defacing the books, to which grievous offense the softer sex is chiefly obnoxious. This more intelligent readers, too, are by no means blameless in this matter, for it appears that some of them are addicted to the vanity of interlining passages and scoring the margin with notes. Elia prattles with affectionate pride of his friend Coleridge's wont to "enrich with annotations, tripping their value," his darling folios; but it should not be forgotten that there are not many Coleridges' among even the critical readers of a library. Good books are always entitled to reverence.

A GREAT MINE IN MONTANA.—The Alice mine is to Montana, according to a correspondent of the Salt Lake Tribune, what the Ontario is to Utah. The mine was bought by the Walker Bros., of Salt Lake City, in 1876. In the following year they built a 20-stamp mill, which has been constantly running since, and has produced up to May 10th, ult., 487 bars of bullion, of 2,000 ounces each, amounting to about \$1,000,000. This fine property has recently been transferred to the Alice S. M. Co., including a 60-stamp mill in the course of construction. The new mill is to be finished early this fall. The great vein of the Alice mine varies from 10 to 70 ft. thick, and the pay ore from 4 to 40 ft. The mine has been opened and explored by 5 levels to the depth of 500 ft., and the main shaft has attained the depth of 700 ft. There still remain immense reserves of ore on all the levels. The upper is probably the most nearly exhausted, and there are yet on that level thousands of tons of free milling ore that it is estimated will yield \$75 per ton. It is probable that the company will soon build a 20-stamp wet crushing mill for the special purpose of working this free ore. All the ore extracted from the mine below the 100 level requires a chloridizing roasting, and this is done by two Howell furnaces. The larger part of the force employed in the mine at present is engaged in the work of exploration, as the ore supply was greatly beyond the capacity of the 20-stamp mill, and there were several thousand tons in the ore-house.

THE SACKETT SCHOOL.—From the first annual catalogue, which lies before us, we learn that the object of the Sackett School is "to do foundation work in education." This is a high and praiseworthy object—for the need of such work is large and growing—and entitles Principal Sackett to the consideration of parents and the guardians of children. A careful reading of the catalogue has impressed us with the belief that just such a school is needed for the training and preparation of youth for the college and the university; a school in which the tuition is rational, thorough and conscientious, and where the moral and physical discipline is judicious without being rigid. The faculty appears to be ample and of a high character, and the course of studies in the various departments is generous without being exacting. Study is diversified by those recreations that youth delights in, and the wholesome food and pleasant comforts of home. Reference is given to a number of gentlemen whose children have been pupils in the school. It is worthy of liberal patronage. The institution is in Oakland, on Hobart street near Telegraph avenue, a short walk from the Broadway station of the railroad.

A VALUABLE HANDBOOK.—We have received from A. L. Bancroft & Co. a copy of a valuable handbook for engineers and practical men. It is entitled "The Slide Valve Practically Explained." It embraces simple and complete practical demonstrations of the operation of each element in a slide-valve movement, and illustrates the effects of variations in their proportions, by examples carefully selected from the most recent and successful practice. The work is by Joshua Rose, M. E., author of "The Complete Practical Machinist," "The Pattern-Maker's Assistant," etc., and is illustrated by 35 engravings. It is issued by Henry Carsey Baird, Industrial Publisher, 810 Walnut St., Phil., and the publication price is \$1, sent by mail free of postage to any part of the United States.

News in Brief.

The Fisk University has graduated six negroes this year.

GERMANY sent England £3,000,000 worth of potatoes last year.

CLOVERDALE is building a small tannery and calls for a woollen mill.

THE Roumanians are setting out forests of young trees. In one place 14,000 have been placed.

A NATIVE of Surrey, N. H., has given \$10,000 to pay the town debt, and \$5,000 to establish a free library.

For the last fiscal year North Carolina spent \$326,040.85 for public schools and had a balance of \$147,170.94.

THE subscriptions to the projected railroad from Stockton to Bodis have been cancelled and the project abandoned.

SOUTH CAROLINA has six flourishing colleges, six female seminaries, three military academies and a colored university.

A cow in Cambria county, Pa., has undertaken the care of seven young pigs that were neglected by their mother.

COL. JAS. DIXON, a member of the Stevenson regiment, was drowned lately while fishing in Gold Lake, Sierra Co., Cal.

NEW YORK humans grocers request their patrons by placards to purchase supplies before 8 P. M., for the sakes of the clerks.

THE El Dorado Republican says that most of the cattle and sheep men have passed up into the mountains with their stock.

A MECHANICVILLE (N. Y.) farmer protects his hen roost from hawks and thieves by keeping a flock of a dozen guinea fowls.

THE new breed of whales reported to have made their appearance in the Arctic seas are larger and tamer than the old whales.

THE Oakwood herd of Short-Horns was sold at Dexter Park, Chicago, July 1st. There were 39 head, which sold for a total of \$60,250.

AT New York, July 1st, the exports of wheat, corn and oats amounted to 1,250,000 bushels—the largest amount ever reached there in one day.

THE Wesleyan Chapel, in City Road London, founded by John Wesley, which was partially destroyed by fire in December last has been restored.

OVER 500 sick women and their little children enjoyed the delicious surf bathing and the hospitality of the Seaside Sanitarium at Rockaway beach, June 26th.

THE Agricultural Association, comprising the counties of El Dorado, Amador, Placer, Nevada, Mono and Alpine, will hold its tenth annual fair at Placerville.

THERE lately arrived in New York city, from Albany, a horse 20 hands and 1 inch high, and weighing 2,450 lbs. He is a dark bay, and without spot or blemish.

THE Santa Cruz papers state that the population of Monterey aggregates 1,400 persons, and that a large majority of those are natives of Mexico and California.

AT Hamden-Sidney College, in Virginia, the Arts degree is to be given hereafter to students who substitute both French and German for either Greek or Latin.

FREQUENT and heavy showers throughout the northwest have already greatly delayed the harvest of wheat, and impeded the cultivation of corn and hay-making.

THE Philadelphia Grand Jury meets with encouragement in its proposition to revive the pillory and whipping post as a means of punishment for petty crimes.

LATELY in New York a 16-months-old child had her ears pierced for earrings, and was immediately attacked by facial erysipelas, from the effects of which she died.

THE first Merino sheep ever shipped from Vermont to Montana were shipped last week from Middlebury, and filled two cars, one load being all registered stock.

SUBSCRIPTIONS are to be raised throughout England for the widows and orphans of the officers and crew of the *Atalanta*. All hopes of the safety of the vessel are abandoned.

TWO-THIRDS of the American tourists now in Europe expect to go to the Ober-Ammergau Passion play. Myriads of English will go there, too, on the Cook excursion tickets.

AT Memphis within three months and a half, 20 miles of sewerage pipes and 30 miles of subsoil drain pipes have been put down, and beneficial results are already discernible.

THE latest reports from the famine districts in Ireland show that many parishes have not yet received any relief at all and that in the month of July there will be a fearful suffering.

THE coinage at the U. S. Mint for the fiscal year ending June 30th was valued at \$84,370,144, of which \$27,934,750 were standard silver dollars. This exceeds the coinage of any previous year.

THE Spanish government will not permit the exiled religious societies of France to establish themselves in Spain near the French border, and elsewhere only after vigorous examination into their character.

THE United States Entomological Commissioners are making preparations to resume the investigation of the Rocky Mountain locust and grasshopper and the cotton worm under the new appropriation of \$25,000.

THE announcement that the Empress of Russia died alone, unattended by any member of her family, and during even the absence of the one servant who was in her room during the night, has given rise to much comment in England.

The Mechanics' Fair Daily.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the ELEVENTH VOLUME of the MECHANICS' FAIR DAILY during the FIFTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Tuesday, August 10th, 1880.

It will be of large size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The host of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resources and rapid progress of our great Western Community.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle by those who receive it freely at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive advertising and printing privileges, and will receive no advertising in the official catalogue and reports.

Our ten previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a mere broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our coast.

DEWEY & CO., Publishers.
Office, MINING AND SCIENTIFIC PRESS, No. 202 Sansome street, N. E. corner Pine, San Francisco.

AN ENTOMOLOGICAL REPORT.—We are informed from Washington that Prof. Comstock's report on entomology has been completed, and will be prepared for publication immediately. The report describes the habits of about 50 species of insects, among which are the army worm and a new species of hopper, which devastated the wheat fields in the South during last spring; it also treats of the habits of several species of insects which are injurious to clover, to forest, shade and fruit trees, and to gardens and vegetables. A preliminary report is made of an investigation of insects which are injurious to orange trees. This highly important investigation was begun in Florida last winter, and will be continued in California this winter. It is an excellent feature of the report of Prof. Comstock that it is written in popular style, and is designed for circulation among farmers. However, the scientific features of each topic discussed are given for the benefit of entomologists.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bollito. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

Quinine and Arsenic

Form the basis of many of the Ague Remedies in the market, and are the last resort of physicians and people who know no better medicine to employ for this distressing complaint. The effects of either of these drugs are destructive to the system, producing headache, intestinal disorders, vertigo, dizziness, ringing in the ears, and depression of the constitutional health. AYER'S AGUE CURE is a vegetable discovery, containing neither quinine, arsenic, nor any deleterious ingredient, and is an infallible and rapid cure for every form of Fever and Ague. Its effects are permanent and certain, and no injury can result from its use. Besides being a positive cure for Fever and Ague in all its forms, it is also a superior remedy for Liver Complaints. It is an excellent tonic and preventive, as well as cure, of all complaints peculiar to malarious, marshy and miasmatic districts. By direct action on the liver and biliary apparatus, it stimulates the system to a vigorous, healthy condition.

FOR SALE BY ALL DEALERS.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

THE BEST NEWSPAPER FILEHOLDER AND ADJUSTABLE BINDER can now be had at this office. It consists of elastic fastenings, with stiff, cloth covered side. Size suitable for a full volume of this paper, \$1. To our subscribers 75 cts., mailed postpaid.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

SETTLERS and others wishing good farming lands for stock crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

FRESH attractions are constantly added to **WOODWARD'S GARDENS**, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Chew JACKSON'S BEST Sweet Navy Tobacco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company,
San Francisco, July 2, 1880.

At a meeting of the Board of Directors of the above named Company, held this day, Dividend (No. 17) of Seventy-Five cents (75c.) per share was declared, payable on MONDAY, July 12, 1880, at the office in this city, or at the agency of The Nevada Bank of San Francisco in New York.

WM. WILLIS, Secretary.

Office—Room 29, Nevada Block, No. 309 Montgomery St., San Francisco, Cal.

DIVIDEND NOTICE.

OFFICE OF THE

Consolidated Virginia Mining Company,
Room 26, Nevada Block, No. 309 Montgomery St., S. F.

At a meeting of the Board of Trustees of the Consolidated Virginia Mining Company, held this seventh day of July, 1880, dividend (No. 52) of Fifty (50) Cents per share was declared payable on THURSDAY, the fifteenth day of July, 1880.

Transfer books closed until the 16th instant.

A. W. HAVENS,

Secretary.

Gover Mining and Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 42), levied on the Fifth day of May, 1880, the several amounts set opposite the names of the respective shareholders, as follows:

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS is called to the new work by JOHN A. CHURCH, E.M. Ph. D., on "The Comstock Lode, Its Formation and History." This very exhaustive treatise on this famous lode is fully illustrated with diagrams and colored charts showing sections, ore bodies, etc., and will be of great interest and permanent value for reference. Dewey & Co., Publishers of the MINING AND SCIENTIFIC PRESS, are sole agents for the sale of the work. Mr. E. M. SLEATOR will act as their agent, and call on Mining Engineers and those interested in the great lode in this city with a copy of the book for their inspection.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Small Sizes made in Sections not to Exceed 300 lbs.

FRUE'S ORE CONCENTRATOR OR VANNER.
Plunger Jigs. Revolving Screens.
CRUSHING ROLLERS. SAMPLE GRINDERS.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, San Francisco, Cal.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarished or gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

Gold Miners

WORKING PLACER, GRAVEL AND QUARTZ MINES,
SAVE YOUR GOLD!

— BY USING —

SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save a very much larger percentage of gold than any other method. Thousands of orders filled and the demand constantly increasing.

Having very extensive facilities for the manufacture of these Plates, will fill orders for California, Colorado, Montana, Dakota, Oregon, Idaho, Utah and adjoining States at prices which defy competition.

Metal Goods of every description, including Musical Instruments used by Brass Bands, plated.

SECURE PATENTS

Through Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

The Hoover Telephone.

We give herewith a pictorial representation of what may be called a mechanical telephone. It is not operated by either electricity or magnetism; but consists of a simple arrangement of metallic diaphragms, placed in intensifying drums and connected by a copper wire. The instrument is known as the "Hoover Telephone." It is being largely introduced and gives very good satisfaction over short distances. Hitherto it has not been used over a space exceeding one mile, but the proprietors have no hesitation in putting it up and guaranteeing satisfaction over much longer lines. This telephone transmits the voice as faithfully and as distinctly as the Edison or Bell telephone, and costs much less, being furnished, with appliances for a call, at the very low price of \$10 each, with an addition of five cents per rod for whatever wire is needed to make the connections between the two points. Ten cents each is also added for such tension springs and hearings as will be required in putting up and sustaining the wires. Insulators, five cents each. A simple telephone, without a call, is furnished for \$5, the cost of wire, insulators, etc., to be added as in the first instance. Figure 1 represents a sectional view of a telephone complete, or rather of one terminus of the same. The mouthpiece, it will be observed, is funnel-shaped, concentrating the sound of the voice at the center of the diaphragm, from whence the vibrations are transmitted by the wire, as shown, to a similar instrument at the other extremity. In the lower portion of the instrument, as shown, there is a mechanical call, which, by the use of a spring, key and pawls, is made to cause a small hammer to beat rapidly upon the inner side of the diaphragm, the sounds from which are conveyed by the wire to the telephone at the other extremity, where they are repeated so loudly and so distinctly as to arrest attention about as readily as the ordinary magneto bell. Figs. 2 and 3 represent a perspective and sectional view of the telephone without the "call." The only method of calling with these instruments is by a rapid tapping of the pencil on the diaphragm. Such a call answers very well for short distances, and where the call is not expected to arrest the attention at any great distance from the instrument.

For connecting an office or store with a factory, a physician's office with a drug store, two private residences, an upper with a lower floor, and for many other uses this instrument answers every practical purpose. It is cheap and can be sent by express, C. O. D., to any part of the country, with all necessary directions for putting it up and operating. We have one of these instruments to connect our editorial rooms in the front with the composition rooms in the rear of a long building, running from street to street. Quite a number are also in use in various parts of the city and in Oakland. Sold in this city by the Hoover Telephone Co., room 24, at 328 Montgomery St. Send for circulars, which will give all particulars.

MINING ENTERPRISE IN UTAH.—At Stockton, in Tooele Co., Utah Territory, the Longmaid smelting works, which have been idle for several years, are being greatly enlarged by Gen. P. E. Connor, as we learn from a correspondent of the Salt Lake Tribune. The old machinery has been removed, and very little of the old buildings will remain after the contemplated changes are made. The new works will be supplied with a powerful engine of 60-horse power and a hoiler of corresponding capacity. Extensive concentration apparatus will form one of the features of the works. They are designed for working the ores of the Great Basin mine, of which property Gen. Connor is an owner. The mine is now yielding large quantities of ore, and the writer pronounces the enterprise one of the most promising and valuable in the Territory.

News has been received from the west coast of Africa that trade has been greatly interfered with by the withdrawal from circulation on the gold coast of all American dollars.

WANTED—MORE THOROUGHNESS.—Thoroughness is the one thing needed in our systems of education. We have far too many clever smart-torers—too many jacks-of-all-trades. One of our critics, himself well equipped for the battle of life, has declared that the difficulty in our America is, that while we are all "pretty well" educated, "very few of us are first-rate and carry as many guns as we might. We forget that if a man does not know a thing accurately he positively does not know it at all." The same authority remarked that during the past 25 years "there has not graduated from any American college a man who has yet made any great mark either as a lawyer, an orator, a statesman, a poet, a preacher, an essayist, or an historian." Inaccuracy is our besetting sin. Such phrases as "pretty near," "about right," "near enough," are rarely heard in any other country, and may be set down as peculiar to Americans. Thoroughness is a marked quality of German training, and German specialists command the admiration and the money of this world. American young men must become more accurate, thorough and downright, or our

FIG. 1.

THE HOOVER TELEPHONE.

places of honor and emolument will be filled by the stranger.

THE SEAT OF COMMOION.—A dispatch from London the 9th inst., announces an earthquake at St. George, one of the Azores, and the formation of another island about 600 yards distant, and some 1,800 square yards in extent. Those western islands have been the scene of violent upheaval and disturbance since they were colonized in the middle of the 15th century. In 1591 there was a violent concussion of the earth during 12 days; and a devastating earthquake occurred in 1757. In 1808 a volcano on the island of St. George destroyed the town of Ursulina; and three years later a volcano appeared in the sea near the island of St. Michael. And an island called Satrina gradually disappeared in 1812. No where else on the globe, perhaps, are the ups and downs of life so marked as on the Azore group.

A CHEERFUL VIEW OF LAKE DISTRICT.—Affairs in Lake District, Mono Co., have assumed a more cheerful appearance since the starting of the Mammoth mill. The Herald says that now, with a plenty of good ore in sight in the mine, and the mill in better condition than ever before, it is reasonable to predict that a long and successful run will be made. The shipment of bullion by the Mammoth company will infuse new life into other incorporations which have stood still while that company bore the brunt of carrying on active operations. The opening of the mill has led to the employment of additional men, and the state of the district is quite encouraging.

The Outlook on the Comstock.

This long-continued depression of the mines of the Comstock has impelled many both at home and abroad to express doubts of their recovery. Some have gone so far as to predict a collapse of the great property. We are told that while dividends have almost ceased to be paid by any Comstock mine, assessments are levied regularly along the entire line; and that these assessments have grown to be a burden too grievous to bear. Assessments are always felt to be burdensome; but this evil is not an unmixed one. There is not much doubt about the statement that a considerable percentage of the shares of the more conspicuous mines of the Comstock are held abroad, nor that there is a very large one in the hands of the men who manage and control them. The bulk of the assessment money is immediately redistributed to miners and laborers and machine shops, as well as to that large class which furnishes material and supplies, and through these various avenues it

FIG. 2.

FIG. 3.

most suggestive. People can draw whatever conclusions they like from the foregoing, but the opinion formed by us when examining the formations in these three crosscuts was that they constituted the top of an ore body, and we have had no reason since to change our opinion.

The facts in the case are likely to be soon known, as the north lateral drift is very near a point under the middle of the crosscuts above made. The intention is to run crosscuts simultaneously in to the ore vein from points 900 and 1,000 ft. north of the incline, and these will be started very soon.

The company is preparing and has been since the crosscuts on the 2300 were run, to open more direct communication through its main shaft with this portion of the mine. The station for the incline rises from the 2300 to the bottom of the main shaft is now excavating, and a contract has been entered into to raise the incline. The distance perpendicularly is 500 ft., although nominally 600, an extra 100 ft. having been added to the lower levels of the mine for uniformity in depth and along the north end.

Of Union it is necessary to say but little, as much has already been said from time to time about this situation there. It is known that the greatest reach and wealth of the ore body in Union was on the sill floor of the 2400 level, which is the farthest down that any positive knowledge of it extends. This fact, however, that the ore formation extends to the drift run to connect winzes No. 1 with the Sierra Nevada incline, that it feathers out even to the line of connection between winze No. 1 and 2, both of which workings were calculated to be beyond it, ought to satisfy everybody that the 2500 of Union will open up well. Few, if any, in this section who are at all familiar with the situation have any doubt about the result of pushing excavations into that portion of the vein where ore is expected, since it has been found where not expected.

THE POWER OF CONSCIENCE.—Recently the Treasury Department received from an unknown and repentant sinner the sum of \$100, with no other explanation than that it belonged to the Government. The money was placed to the credit of the Conscience Fund. It is stated that since the close of the civil war the contributions to this fund, always from unknown persons, have reached about \$200,000. One day as high as \$11,000 were received, and several times the receipts to the fund have been \$5,000 on a single day. Sometimes the person sending the money confesses that he has smuggled goods or has defrauded the Internal Revenue, and that the sum that he returns rightfully belongs to the Government. These acts of restitution, though quite too few and far between, are refreshing evidence of the power of conscience.

GROWTH OF AMERICAN AGRICULTURE.—The enormous growth of our agriculture is shown by a writer in the *International Review*, whose figures, pending the publication of the census returns, may be accepted as trustworthy. Our authority says that in 1865 the wheat crop was 148,543,000 bushels; in 1879, 418,756,000. Corn in 1865 was 704,427,000 bushels, and in 1879, 1,544,000,000 bushels. Within 30 years the corn center has been transferred from the South to the West, and the wheat center from the Middle States to the West. The tobacco increase has, of course, been in the Southern States. Within the same period the cotton crop has increased from 3,012,000 bales to 5,216,000. Arkansas and Texas are the largest gainers from the increase in cotton. The total exports of all grains have risen from 39,000,000 bushels in 1878 to 189,000,000 bushels in 1879.

A PROMISING QUARTZ CLAIM.—There is considerable promise about the Bulow quartz claim, near Jones' Bar, on the South Yuba river. We learn from the Nevada Herald that two tunnels have been driven on the claim, and each one on a different ledge. In tunnel No. 1, which is 70 ft. long, there is a ledge 5½ ft. wide, which contains a heavy percentage of sulphurets, and carries besides free gold. In tunnel No. 2 the ledge is irregular along the 20-ft. run, but the croppings warrant the belief that it will yet prove as good as that found in No. 1.

returns again to general circulation. That part of the money, be it great or little, which comes from the outside holder of mining shares is an unmixed good to the community.

In the meantime the necessity for assessments on some of the mines, especially on several at the north end, was never before so apparent. The difficulty of carrying on explorations at a great depth and in the presence of a vast volume of water is costly business. It appears to be at the north end of the Comstock that favorable developments are now looked for, and how far this expectation is justified the annexed intelligent and clear review of the situation by the Gold Hill News will show. To enable the reader to understand the posture of affairs in Sierra Nevada, the writer gives just a brief sketch of operations on the 2300 of that mine. In the crosscut run east 900 ft. north of the incline on that level, nine ft. of clean milling ore were found. In the crosscut 100 ft. further north, came first a streak of ore averaging \$10 in value and three ft. in width. Beyond this there was found four ft. of ore averaging \$20 per ton. Still further east there was another streak five ft. wide which averaged \$40 per ton. The whole width of the ore vein was 70 ft. Of the ore cut by the crosscut, 30 carloads were saved which gave an average of \$43.75 per ton. Some of the ore went well into the hundreds, and many assays were from \$250 to \$300. One hundred ft. still further north another crosscut was run, but only a short distance. A diamond drill was then sent ahead and brought out rock which ran from \$5 to \$10 as an average, but showed some good ore.

From the foregoing it will be seen that for 200 ft. along the vein there is ore. The streaks are

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eps

Notes from Plumas County.—No. 1.

EDITORS PRESS:—No attempt is made to furnish a full account of the mines of this section. Others on the ground, more familiar with the facts, promise to follow with some very interesting details of several important enterprises, among which are a few rich and unexpected developments.

Sons of your readers will remember the richness of the placer mines at old Elizabethtown, two miles from Quincy; in their palmy days giving support to 2,000 inhabitants. For many years the town and its mines had almost been lost sight of, only a very few remaining, who still had faith in the untold wealth that might be eventually unearthed from the deeper channels or from quartz discoveries in the neighborhood.

Rewards of Perseverance.

Messrs. Laavitt & Loring, after six years of prospecting on the old Elizabethtown channel, have at last been amply rewarded for their pluck and perseverance. Their claim is now yielding \$20 per day to this pick. They have run 6,000 ft. of tunnel and sunk 13 air shafts, seeing, in the meantime, many a dark day and struggling with difficulties well nigh insurmountable from the quicksand and the quantity of water to contend with. When the sinking was retarded by these causes, a long drill was driven down to the drain tunnel and replaced by gas pipe, made into four-ft. sections, allowing a section at a time to be taken off in the tunnel below as the work of driving down the pipe and the sinking continued; in this way keeping the shaft comparatively dry for further progress in their operations.

How a Rich Quartz Lode was Found.

It is now a settled fact, that wherever rich quartz gold is found in the canyons, a good quartz lode may be looked for at no great distance above in the mountains adjacent. Its truth is further confirmed by the late rich strike in Mr. Edman's mine, near Meadow Valley; as also in the famous lake claim of Mr. Heath, 10 miles from Quincy, in the opposite direction, from both of which you may expect to hear more hereafter.

The old Betsy gulch, of Elizabethtown, was particularly distinguished for its richness in quartz gold (one piece found weighing over 100 ounces), leading, as I am informed by Mr. Lewis Bell, to the location of what is known as

The Bell Mine.

Which has since passed into the hands, chiefly, of citizens of Dubuque, and has been incorporated under the laws of the State of Iowa. In accordance with Mr. Bell's statement, red croppings were visible on the surface, the ledge being laid bare finally, after many long years of search, by following up the gulch and sluicing off the sides of the mountain; the quartz of the lode carrying gold corresponding, in every particular, with the quartz gold in the gulch below. The company has a first-class 10-stamp mill, and has opened the mine by two tunnels, the upper 700 ft. to lower 400 ft.—finding good ore in each. It is understood that a quartz nugget was once found in the upper tunnel of 14 ounces, yielding \$100 in gold, and that the mill at one time, in a three-days' run, cleaned up as much as \$1,793, giving evidence of some very rich chimneys in connection with large bodies of lower grade ores.

Very recently a considerable body of what is thought to be very rich ore has been laid open; the pay chute some 20 ft. in width, length not yet ascertained. Quartz of better promise has seldom been met with. The formation is slate and porphyry, and the general surroundings all that could be wished for. The distance in places between walls is 60 ft., the best ore outside of main pay chutes lying along or near one or both walls. If the rich chimneys are followed down and the best ore selected from other portions of the mine, as at present intended, the company has every reason to hope for "a good time a-coming." May they see the day when it will rank among the best-paying mines of the State. They are also prospecting by shaft another lode about one mile from the mill. It is represented as 10 ft. in width, the ore running about \$10 to the ton.

You may expect some account of the mines near Greenville, Plumas county, next week.

A. C. K.

Notes from Shasta County.

EDITORS PRESS:—In my last I said I would give you the facts in reference to the silver ledges recently found in this county. The papers have sparingly spoken of it, but many things I have seen in print are like the stories novel writers tell—hard to believe. Since I wrote you last I have been on the mountain and made frequent assays of the rock found.

There is a peculiar mountain about $\frac{1}{2}$ miles north of Shasta known as Iron Mountain. It has always been regarded as of little value until it should be desired to work it for the iron it contained. But during the last winter a Mr. Sulet, an assayer, had been investigating its

merits, and he made the discovery that it contained large amounts of silver as well as iron. Some of the rock has been brought to this city and is being worked. The mountain is about 3,000 ft. above the level of the sea, and is somewhat difficult of access, but by a trail from Whiskeytown, is comparatively easy of ascent.

The ledges are well defined and of enormous proportions. We approached it first at the discovery claim, where the ledge is easily 150 ft. wide and crops out to the height of 1,000 ft. Where the discovery claim is opened it shows a grand mass of iron and silver. Assays of it have been made of very high figures—from \$10 to many hundred of dollars per ton, so I am told. I have made assays from \$10 to \$115 per ton in silver, and also some gold. I have made no assays of the richest appearing rock. The ledge is plainly visible on the surface for two or three miles, and the belt is all located for four or five miles. Such has been the rush, that prospectors have located everything that had the appearance of anything similar to that rock. There is doubtless a very large and very rich silver deposit here, but to my mind it will be difficult to work on account of the prevalence of iron. The iron is in excessive quantity. Where the discovery ledge or claim is opened there is a curious spring which flows as from a hydrant, coming out in a beautiful jet or stream 2 or 3 inches in diameter; and in the afternoon of each day, about 2 P. M., it commences to flow far more rapidly and this jet rises from the surface to a height of 4 ft. and thus continues to flow for 2 or 3 hours; showing that at its head, or in the mountain, a cavity fills up during the day and night, and, when filled to a certain height, adds additional pressure by the condensing of the air in the cavity, and when it is exhausted the spring flows as usual until a recurrence of the same cause produces the same phenomenon. Many men of means have already visited these mines, and arrangements will be made for their early development.

There is not a gulch or creek in any of the mountains around this part of the country that has not at an early day paid richly in gold, and some of them have shown some silver. The people now are looking up the sources of the precious metals, and very many rich gold ledges are being discovered. A new era will soon dawn on Shasta county.

Shasta Co., Cal., June 23, 1880.

A Great Gravel Deposit.

Not many people even in this community, says the *Calaveras Chronicle*, realize the magnitude of the operations at the famous Eureka hydraulic mine, in this county. It is the largest and best appointed hydraulic company in the southern mines, yet the managers contemplate a colossal enterprise. At the present time there is a force of 40 men employed on the claim day and night; and two "giants" spouting 1,000 inches of water, under a pressure varying from 150 to 300 ft., are thundering away at a bank of auriferous gravel averaging about 40 ft. in depth. No adequate idea of the force of these hydraulics can be obtained without a visit to the mine. To look at the bank it seems impregnable; but as the huge streams of water, with a rush and roar like that of a cataraet, are precipitated against it, the solid gravel melts away like the bank account of a prodigal. Acres upon acres have been washed away, the Calaveras freighting the debris down stream, and yet the claim may be said to be just fairly opened. Practically speaking there is no limit to the bed of gravel, and in all human probability the Eureka will be profitably worked a quarter of a century hence.

Water is supplied by two ditches belonging to the mine. One, five miles in length takes water from the Calaveras, while the other extends to Rich gulch and is supplied from Clark's great canal, via Railroad Flat. From the ditches to the mine the water is conducted in huge iron pipes, solidly riveted together, varying from 11 to 15 inches in diameter. The water privileges connected with the Eureka are invaluable and have much to do with constituting it one of the most promising gravel mining enterprises in the country. The water rights embrace both the Calaveras and Esperanza rivers, sources capable of supplying 1,000 inches of free water the year around. As we have before stated the Calaveras ditch is already dug, and the conduit destined to tap the Esperanza is completed to Rich gulch. A short distance further and it will enable the Eureka proprietors to utilize the waters of the Esperanza in reaping their golden harvest. When it is recollected that the cost of 1,000 inches of water, if it had to be purchased, would amount to something like \$125 per day, some idea of the advantage conferred by free water in a hydraulic claim can be obtained.

But we have not half stated the possibilities connected with the Eureka and its water privileges, neither can we give anything like a pen picture of them within the limits of this article. We will simply say that it is in contemplation to finish the Esperanza ditch to that stream and then continue the canal along down the ridge below the Eureka, ultimately throwing the water on to the rich placers of Pine Peak. All along the line of the ditch, which will traverse one continuous gravel bed from first to last, hydraulics can be established, which with the advantage of free water cannot fail to be remunerative. The enterprise is one of the most promising, attractive and feasible of any ever mooted in this section, and we do not know of a scheme anywhere that can equal it as a practical mining investment.

The Freeland Quartz Mine.

This mine, situated in Clear Creek Co., Colorado, has lately attracted the attention of mining men on this coast by the method adopted to utilize the low-grade ore produced. The concentration works of the company are pronounced to be both efficient and economical, and the *Georgetown Courier* gives this account of the mine and the method of reducing the ore.

The Freeland level, the lowest and main working level of the Freeland mine, is now in over 1,800 ft. horizontally and the breast has reached a perpendicular depth of about 925 ft. There remains about 650 ft. of unexplored ground, at this level, between the breast and the western boundary of the company's property, and when the boundary line is reached the depth gained from the surface will be nearly 1,100 ft. The level is now being driven at the rate of 140 ft. per month, and if the present rate of development is kept up during the coming six months an average of 3,850 fathoms of ground will be opened each month.

The Minnie level, 225 ft. above, is in about 1,730 ft., and 250 ft. from the westerly boundary. The average height of the back-stope of the Freeland level is about 40 ft., and of the Minnie, 20 ft. The ore vein exposed throughout the mine ranges from six inches to three ft. in thickness, and is composed principally of iron and copper pyrites, the amount of galena being too small to justify separation. It is gratifying to note that as depth is gained the quality of the ore is improving. About 20 sacks of picked ore composed principally of erubescite are taken monthly from the mine. [Erubescite is a variegated copper pyrite, of a pale reddish-yellow color, and is composed generally of copper, sulphur and iron; owing to its color the mines of Cornwall call it "horse-flesh ore."] This ore will mill all this way from \$700 to \$1,500 per ton, and runs from 25% to 35% in copper. About 10 tons of first-class ore, worth \$80 per ton, and 150 tons of concentrating ore are mined daily, the product of the mine being limited to the capacity of the company's mill and the old Collom mill, just above Idaho springs, which treats 35 tons per day. By concentration 2 3-10 tons of crude ore are reduced to one ton of concentrate, which is worth about \$60 per ton. Drifting and raising is done by contract at a uniform price of \$3.50 per ft. The etoping is done by men employed by the day, there being 63 men employed at that work.

The general plan for sinking a deep shaft, commencing at the Freeland level, has been definitely arranged. The main shaft is to be 6 1/2 ft. in size, substantially cribbed with 12-inch timbers, and machinery will be employed capable of going to a depth of 2,000 ft. A giraffe capable of holding 12 tons of ore will be used for hoisting. It will run upon T-rails laid upon the incline of the lode, and the ore will be discharged into cars and taken to the mill. The mine has paid its first quarterly dividend of \$50,000, and there is no reasonable doubt but the amount can be kept at that figure.

The Freeland concentrating works are acknowledged to be the best in the State. The mill is situated at the mouth of the Freeland tunnel, and all of the ore from the mine is delivered direct to the mill. The concentrating is effected by 12 Hartz jigs for the coarse ore, and a bundle for the slimes, the expense being 70 cents per ton. The company is contemplating the erection of a 15-stamp mill at the mouth of Trail run for the purpose of treating tailings from the mill, which contain something over \$3 per ton. The process will be to recrush the tailings and reduce them to fine sand, and to then concentrate again in jigs and on buddles.

CONGRESSIONAL WISDOM.—One of the latest, and it may be added, most superfluous, resolutions offered in the late Congress, says the *Engineering and Mining Journal*, was one by Mr. S. S. Cox, to the effect that American capitalists who subscribe to the \$60,000,000 of Panama Canal stock, offered them by the sanguine M. de Lesseps, will commit an unwise and unpatriotic act. Mr. Cox has the reputation of being something of a humorist, and his resolution may possibly have been presented in a Pickwickian sense. On any other presumption the resolution is incomprehensibly unnecessary. The idea conveyed in the resolution that there could by any possibility be any sympathy between capital and any other consideration than profit, must have been intended as a subtle joke.

HIGH RAILROAD SPEED.—In a recent discussion of the question of high railroad speeds, at the Franklin Institute, Prof. Marks stated that he had made some calculations as to the maximum speed at which locomotive engines could be driven before the centrifugal force on the tires of driving-wheels would become so great as to cause them to burst. These calculations, which were approximate only, gave a limit of speed in the neighborhood of 150 miles per hour; of this, 78 miles, or more than half, has already been attained.

A SMALL LOCOMOTIVE.—A diminutive locomotive has been constructed at Pittsburg, Ohio, for Arizona. The cylinders are only six inches in diameter; and the engine, which will draw 150 tons on a level, is intended to haul gold and other ores from the mines to the melting furnaces of its owners, Messrs. Frendenthaw & Co., a distance of four miles.

Low-Grade Ores of the Comstock.

Undoubtedly the working of the large areas of low-grade ores of the Comstock should be undertaken. The working of such ores would give employment to a host of miners now idle, and would give to the world millions of dollars in gold and silver now lying in the old levels and croppings of the Comstock. The working of these ores is again being advocated by the press of San Francisco. It is thought the Miners' Union should appoint a committee to confer with the mine managers in regard to the labor situation, and so arrange matters that members of the Union would be allowed to work at points above this level of the Suto tunnel at \$2.50 or \$3 per day, or at rates of wages in accordance with the character of the ore extracted. We desire as much as any one in San Francisco to see the business of working our low-grade ores commenced, and have advocated the trying of the experiment from the first; but the inauguration of the work does not lie with the Miners' Union. The first thing to be done is to put up proper mills and works for the concentration of low-grade ores. Let this be done, and an arrangement will speedily be made for furnishing ore for such works.

Should the Miners' Union hold a meeting tomorrow, and say that half their members, or as many as are now out of employment, would be allowed to go to work at taking out low-grade ores, there would be no one to give any of them a day's work. This being the case, it is not likely that the Miners' Union will at present pay any attention to the matter. However, let men of capital start in and put up proper works for the reduction of our low-grade ores, and show that they will be able to give employment to 1,000 or 2,000 men, and then something will be done.

Should the erection of works be commenced at once it would probably be nearly a year before there would be a demand for miners to take out ores for concentration. This being the case, no one need expect that the Miners' Union will call a meeting and reduce wages in advance of the demand for men. Should they be asked to do so, they would feel that there was some trick in it, and, knowing that once wages are knocked down it is no easy matter to bring them up again, would have nothing to do with the business.

It would be commencing at the wrong end. The mill first, and then the men to keep them supplied with ore. An arrangement for mining the low-grade quartz can doubtless be made. The fairest way for all concerned may yet be found to gauge the wages of the men in accordance with the amount of pay that can be obtained from the ores worked.

Thus far all is talk. If any man or company of men intend doing anything with the low-grade ores of the Comstock, it seems to us the first move should be to begin experimenting in the concentration of low-grade ores. For this preliminary part of the business temporary experimental works should be erected, and samples from areas of low-grade ores in the leading mines should be taken out and worked, or such samples should be sent to the best concentration and reduction works now in operation anywhere in the United States or Europe. Something of this kind certainly should be done before erecting the large and costly works that would be needed for working the low-grade ore on the grand scale that would be required.—*Territorial Enterprise*.

HOW OUR FORESTS DISAPPEAR.—The manufacture and shipment of timber is a leading industry in western Washington Territory, employing a great many workmen and an immense number of large saw mills, operated by steam and water power. A large fleet of ships and some small exporting steamers convey the timber to San Francisco, East Indies, Europe, Australia, Egypt, South America, Japan and China. The timber shipped from one district in western Washington (Pugnet Sound), in 1876, by vessels, without reckoning home consumption, equalled 40,000 railway carloads, or 2,000 railway trains of 20 cars each, and 1878 amounted to 250,000,000 ft. Timbered lands, well situated for logging purposes, sell at \$8 to \$12 per acre; three miles from a river timber lands can be had at \$2 to \$3 per acre.

HONORS TO AN AGED CHEMIST.—The chemists of Germany are collecting money for the purpose of presenting a gold medal to Prof. Woehler on his 80th birthday, which will be July 31, 1880. Prof. Woehler is one of the most distinguished, as well as the oldest, of living chemists. Himself a pupil of old Berzelius, a contemporary of Liebig, and the loved instructor of many of our best chemists, his name is equally respected on both sides of the Atlantic. Prof. Jay and Chandler, of Columbia College, New York City, two of his former pupils, are receiving contributions from those who wish to join in this well-deserved memorial.

A BIG BLAST.—The big blast at the Blue Tent diggings, that has been so much talked of during the past week, was fired off July 2d. The charge consisted of 1,542 kegs of powder, at 25 pounds to the keg, making in all 38,550 pounds. This firing was done by electricity. The result was a very successful one. The bank which is 238 ft. perpendicular, was torn away for about 150 ft. back, and 200 ft. wide. It is believed that this is the largest piece of ground torn from its foundation in one blast that has ever taken place in California.

MECHANICAL PROGRESS.

Improved Flour-Mill Machinery.

Until recently it was believed that the only thing to be sought for in the production of a good article of flour was a more or less fine disintegration of the kernels of wheat. As long as millers held to the theory that "grinding" was all that was required, a large percentage of the flour had its nutritive powers greatly reduced by being ground to an impalpable dust. Science, by aid of the microscopes, has shown that no really good bread can be made from flour in which any large portion of the starch globules have been thus broken down. The rising of bread is due to the starch globules which remain whole, while the dust from the disintegrated ones, by souring, impairs the lightness and sweetness of the loaf. It is but recently that these facts have been made known to millers, and since that time they have been discarding their old theories and machinery, and devising improvements with the view to separating the starch globules, rather than pulverizing them. Another important advance in this industry consists of an improvement in holting machines. Until recently the bran was separated from the flour by a powerful air-blast, which blows off the light particles of bran. Considerable power is required for this process, and although it is carried on in a closed room, there is not only a great waste of the finer particles of flour, but the impalpable dust penetrates every part of the mill, and often gives rise to destructive explosions. By a recent invention, electricity is made to take the place of the air-blast. Just over the wire bolting-cloth, which has a rapid reciprocal motion, a number of hard rubber cylinders are kept slowly revolving and rubbing against strips of sheepskin, by which a large amount of frictional electricity is evolved. Then, as the middlings are sieved by the reciprocal motion, the lighter bran comes to the top, whence, instead of being blown away by an air-blast, it is attracted to the electrically-charged cylinders, as light substances are attracted to a piece of paper, or a stick of sealing wax, which has been smartly rubbed. The removal of the bran from the rollers and its deposit on one side are readily effected, while the flour is carried in another direction. The separation is thus made complete, with very little loss or dust. Still another device has also been introduced to remove from the wheat, before being ground, small pieces of iron, which, despite the utmost care, will find its way into the grain, working great injury to mill machinery. This trouble is now remedied by the use of a series of magnets, directly under which all the grain is made to pass. These magnets readily capture all the stray pieces of iron from the wire hands used in hindlag; and they have also revealed the singular fact, that, of the scraps of iron and steel which find their way into the grain, fully one-third are something besides the hindling wire. They are of larger proportions, of varying character and much more harmful to the machinery than the wire. Thus it is that science is constantly coming to our aid in all our varied industries, lightening the labor of the workman, decreasing the cost of products, and in every way improving all the various processes which are involved in the improved and constantly advancing civilization of the age.—*Californian for August.*

Railroad Car Wheels.

There appears to be no record which shows the first form adopted for the flanges of railroad wheels, nor of the shapes which they have gradually assumed. Wood's treatise on railroads and Pambour's book on locomotives contain sections of tires, the form of which does not differ materially from those now in use. These were published in 1836 and 1838. The fact seems to be that the present shape of flanges and also of rails has been assumed to be right without any good or sufficient reason for it, excepting that it worked well in practice. In other words, there are no adequate reasons for inferring that the present form of wheel flange is the best that is possible. It has been adopted empirically, and there is no sound theory to recommend it. It seems quite within the range of possibility that an elaborate investigation might indicate some important and valuable modifications in the form of these very important parts of all railroad vehicles.

There are more than 10,000,000 car-wheels in use in the United States, the average life of a wheel is eight years, and it requires a little over a ton of pig iron to make four wheels. Hence, assuming that the number of wheels in use is even 10,000,000, it requires 1,250,000 new wheels to replace those worn out each year, and to make these over 312,500 tons of pig iron are required. As 1,250,000 wheels are worn out each year, and as the average weight of a worn out wheel is about 515 lbs., something like 287,389 tons of this old material are available for remanufacture. The difference between this sum and 312,500—the approximate weight of the new wheels—shows pretty correctly the number of tons of new material consumed per year in the manufacture of car wheels, assuming that all the old wheels are manufactured into new ones. The difference is 25,111. The life of a car wheel is, however, growing shorter, for

two reasons: 1. The increasing weight of a carload, this load on some roads now being double what it was a few years ago; and second, better management and improved loading and unloading facilities, by which the wheels are kept moving more continuously than formerly. As an instance, a train loaded with petrolsams can be unloaded at New York in a very small fraction of the time required before the excellent facilities for discharging were provided. Manufacturers guarantee wheels to run from 50,000 to 60,000 miles, but they not unfrequently greatly exceed this.

AMERICAN PLATE GLASS.—The manufacture of plate glass is quite a new industry in this country. There are as yet but four companies in operation. The Pioneer and the largest works of the kind is located at New Albany, Indiana. It occupies 20 acres of ground, and employs \$1,000,000 of capital. Connected with the works, and under the same management, is another, known as the De Pauw Plate Glass Works, with a capital of \$750,000. These two establishments give employment to upward of 1,000 persons. The Ford Plate Glass Works, at Jeffersonville, is operated by a capital of \$600,000, and the Crystal City Works, near St. Louis, employs a capital of \$750,000. This industry is an important one, and as yet furnishes but a very small portion of the plate glass consumed in the country. That it is profitable may be inferred from well authenticated reports that the most strenuous exertions have been made, by importers and foreign manufacturers, to crush out the business of home manufacture. It is said that efforts have been made, by a combination of those interested in the foreign manufacture, to purchase all the American factories, with a view of tearing them down, and establishing a monopoly of the business in the hands of the foreign manufacturers. Large sums of money, it is also said, have been spent in sustaining a strong lobby at Washington, to bring about either a material reduction or a total abrogation of the tariff on foreign plate glass. It is to be hoped that a business of so much and such growing importance will be fostered by the Government until it shall be able to take care of itself, an advantage which, under proper auspices, it will reach in a very few years.

ELECTRO-DEPOSITION AS A SUBSTITUTE FOR CASTING.—We find, in *London Nature*, an interesting reference to the process of electro-deposition, which, in the hands of an electro-metallurgical company of Brussels, promises to become a practical substitute for casting in the production of bronze statuary. Our contemporary confirms our previous statement that this company had succeeded in producing a colossal statue of Van Eyck by the deposition of copper electrically upon the clay model. The same authority notices a simple procedure by which the production of bronzes on the small scale may readily be carried out. Take any plaster figure or group, boil in stearins, then coat well with black-lead, and place in the copper bath as in ordinary electrotyping. Attach a very weak battery, and deposit very slowly a thin coating of copper. Then remove from the bath and bake in an oven until the plaster model shakes out in dust. There remains now only a thin copper shell of the model. Varnish this on the outside to prevent further deposition there, and replace in the bath, with a much stronger battery power. The copper will now deposit on the inside, and when the same becomes thick enough, the process is finished.

A somewhat remarkable machine is described in a late French technical journal. It is called a "profilograft," because when in use it traces mechanically on paper the outlines of the ground over which it travels. It is described as a small carriage, mounted on two wheels, drawn by one man, and attended by another who marks the levels at the proper places; and underneath hangs an iron rod, with a large ball at its lower end, serving as a pendulum. This pendulum maintains a constant vertical position, while the machine inclines in one direction or the other according as it ascends or descends a slope. To the upper end of the rod is fitted a pencil, which marks on a sheet of paper the ups and downs of the country traversed, whether on an ordinary road or across trackless fields. The exact profile is thus recorded to a given scale. At the same time one of the wheels, acting on the part of chain bearer, measures and indicates the distance traveled throughout the survey. For surveyors and others engaged in leveling operations, this machine would appear to be eminently serviceable, and there is talk of its being made use of in a new general survey of France contemplated by the government.

COMPRESSED AIR AS A MOTOR.—This question of the economy of the use of compressed air as a motor, is about to be tried on an extensive scale at Rochester, N. Y. A large company has been formed in that city, which has purchased an extensive water power to be utilized in compressing air, which will be conveyed in pipes to the various manufacturing establishments and machine shops of the city, to be used as a motor in place of steam. It will also be used for the propulsion of street cars.

TO CUT SHEET BRASS.—Moderately thick plates may be cut chemically by drawing a line or mark with a solution of mercury in nitric acid. The acid attacks the copper, while the mercury amalgamates with the zinc; this seems to be the explanation; at any rate, the brass becomes as brittle as glass on the place where the line is drawn, and is easily broken off.

SCIENTIFIC PROGRESS.

Lightning and Oil Tanks.

The frequency with which the large oil tanks in the oil regions of Pennsylvania have lately been struck by lightning, and the immense losses of property thereby entailed, has elicited much discussion, both in regard to the inciting cause of such destruction, and also in efforts to reach some reliable means for averting such occurrences. Whenever a thunder-storm passes directly over one of these tanks it seems devoted to destruction, and millions worth of property has thus been destroyed. No practical safeguard has yet been suggested. The most approved rods placed upon masts far above the tanks, and completely surrounding them, and also well grounded in the earth, seem to be useless, although affording almost perfect protection under other circumstances. It is well ascertained that the mass of iron present has nothing to do with the attraction of the electrical discharges. The *Scientific American* has given what appears to be the most reasonable explanation, as follows:

"From every oil tank, according to our theory, there is a constant escape of light hydrocarbon vapor, which forms a permanent cloud or column, rising to a great height above the tanks, far above any rod that could be erected. This vapor rod is a conductor, which the lightning naturally follows, sets on fire the vapor, and explodes the tank. A column of heated air or vapor rising from a chimney is well known to be a conductor for lightning; the rise of hydrocarbon vapors is illustrated by the balloon. If the theory we have outlined is correct, the remedy for the electrical explosion of oil tanks is to be found in such treatment of the oil, or such a construction of tank, as shall prevent any escape of the light vapors."

The *Iron Age*, in noticing the above, says: "This column of vapor rises only from tanks with wooden tops; or, in other words, an iron-top oil tank is never struck by lightning. This is a remarkable fact, and points out the remedy against the origin of these fires. We have carefully watched them, and speak from positive knowledge of all tank fires that have been caused by lightning during the past seven years, except the one at Titusville early this month, and we state with confidence that an iron-top tank has never been struck by lightning. Of the Titusville fire we have no positive knowledge on this point, but, judging from the locality and the size of the tank struck, we should say that it was a wooden-top tank. There is also one case, we believe, in which an iron-top tank was fired by lightning, but in this case the lightning struck a pipe leading to the tank at a point some distance from it. In a word, the remedy for these oil fires caused by lightning seems to be the changing to iron of all wooden-top tanks."

NEW METHODS OF USING VOLATILE DISINFECTANTS.—In the Parkes Museum of Hygiene, at London, there are two appliances for charging the air of a room with antiseptic vapor. One consists of a miniature "round towel" circulating on two rollers, the lower of which rests in a trough filled with a solution of carbolio acid or any other soluble disinfectant. The other apparatus consists of a metal box filled with Norwegian tar. The lid of the box is provided with metal laminae, which are immersed in the tar. When the apparatus is to be used the cover is raised, and the tar-covered laminae are exposed to the air. The pleasant odor of the tar is very quickly perceptible throughout the room. A tube is fitted to the box, also, which enables it to be used as a simple inhaler, and on applying the mouth to the end of the tube, and drawing an ordinary breath a very perceptible dose of the tar-vapor is obtained.

PROGRESS OF ELECTRIC LIGHTING ABROAD.—The Brush electric light has been introduced into the South Kensington Museum, in London, and the results are very satisfactory. The experiment has been tried in the hall containing the new fresco by Sir Frederick Leighton, P. R. A. There are eight lamps, three suspended on each side and two in the central line, so that the light is equally diffused. The use of the electric light is spreading. The Victoria docks and Holyhead harbor are to be lighted by electricity. The Royal Navy is adopting Brush's light. Siemens's light has been introduced into the Siam Dispensary, Bangkok, as a rival to Jablochhoff's. The arrival of summer has brought with it a discontinuance of the Siemens light in the reading-room of the British Museum until next autumn. The authorities regard it as a good success.

THIN ROLLED IRON FOR SCIENTIFIC PURPOSES. In experiments made at the Allghany observatory, by Prof. Langley, on the measurement of radiant heat, he made use of a thermo-electric apparatus, a product of the American iron industry. Observations made with such instruments have shown that iron in extreme thinness is the most suitable material to be used with them, and in order to supply this demand the Pittsburgh mills have succeeded in manufacturing rolled iron which is so thin that from 10,000 to 12,000 sheets laid on each other equal only one inch in thickness. An instrument made out of this material has almost the same responsiveness to radiant heat which the eye has toward light.

A NEW NEBULA AND A LOST PLANET.—Dr. Temple, of the Observatory of Arcetri, Florence, announces his discovery, on March 14th, of a new nebula, which he at first mistook for a faint comet. Its position for 1879 is R. A., 11h. 18m. 5s., N. P. D., 86° 1' 4". Dr. Temple describes it as a double nebula, with two small but distinct nuclei from 15" to 20" apart, and has added that nebula Herschel II. 32, which is in the vicinity, is much smaller and fainter than the one just discovered. It occasionally happens that celestial bodies are lost as well as found. This has occurred several times in the case of the small planets between Mars and Jupiter, which now number nearly 200. There is one of these, however, which, according to Mr. Proctor, astronomers would regret to lose. This is the planet Hilda, which travels in a much wider orbit than any of the others, and can give more exact information respecting the mass of Jupiter than any other member of the solar system, coming much more fully at certain times under his influence. Unfortunately, Hilda has been searched for in vain at its first return to opposition, and astronomers begin to fear that the planet is, for the time being, lost.

ARTIFICIAL VANILLA.—The production of any well-known substance artificially by the synthetic chemist, is generally viewed by the public with opposition, until convinced that it is identical with the natural product. A German paper produces an indorsement of artificial vanilla by Prof. Meidinger, who says it possesses undeniable advantages over natural vanilla. The latter loses its aroma, is unequal, and the natural bean only contains 2% of valuable material, with 98% of worthless or even injurious material, of which the removal is troublesome and tedious, before the pure flavor can be obtained. In Germany the vanilla is mixed with sugar, and put in packages of different strength for different purposes. That for chocolate manufacturers is 70 times as strong as good vanilla; that for family use is put up in packages equal to one bean, and sold at nine cents each; that for liquor manufacturers 2% of vanilla. Dr. Meidinger speaks very highly of this artificial vanilla, which he pronounces perfectly wholesome.

GLYCERINE CEMENT.—According to *Dingler's Journal*, Prof. Morawski finds that the cause of the hardening of glycerine cement is the formation of lead glycerine, a salt of glycerine and lead oxide. This crystallizes in fine needles, and is formed according to the following equation: $C_3H_5O_3 + PbO = C_3H_5PbO_3 + H_2O$. The greatest hardness is obtained by adding 5 cc. of glycerine to 50 grammes of litharge. If more glycerine is used, the mass solidifies more slowly, and never gets so hard. To obtain a quickly-hardening cement, two volumes of water should be added to five volumes of glycerine, and 6 cc. of the mixture incorporated with 50 grammes of litharge.

SCIENTIFIC PRIZE AWARDS.—A committee appointed in 1876 and presided over by M. Dumas, have reported to the French Chamber of Deputies in favor of granting the first Volta prize of 50,000 francs to Prof. Graham Bell of telephone fame, and the second prize of 20,000 francs to M. Gramme the well-known inventor of the dynamo-electric machine bearing his name. The first one to receive this distinction was Ruhmkorff.

SCIENCE AND COMMON SENSE.—"Common sense," says Prof. Huxley, "is science exactly so far as it fulfills the ideal of common sense; that is, sees facts as they are, or at any rate without the distortion of prejudice, and reasons from them in accordance with the dictates of sound judgment. And science is simply common sense at its best; that is, rigidly accurate in observation, and merciless to fallacy in logic."

"SALICYLIC" OR "SALICILIC?"—The *Louisville Medical News* raises the question whether the current form *salicylic* is consistent with its derivation from the Latin *salix*, the genitive of which is *salicis*. Clearly the spelling should be *salicilic*, after the analogy of *salicine*. It is not easy to understand how the other orthography could have arisen.

THE SUN'S SIZE.—The huge size of the sun, as compared with the earth, may in some degree be realized by this construction of a very simple model. When we take a ball of three inches in diameter as representing the sun we have to place 30 ft. from it a minute ball of 3-100th of an inch in diameter, representing the earth and its distance from the sun.

MAGNESIUM IN STEEL.—A half per cent. of magnesium changes coarse-grained into fine-grained steel and greatly improves the quality. The magnesium is introduced through an opening in the cover of the crucible, after inserting some small bits of charcoal, in order to remove the free oxygen. Without this precaution there would be danger of an explosion.

If the authority of foreign scientific journals is to be accepted, certain water beetles have been found living in reservoirs containing a concentrated solution of sulphate of soda; the liquid proved rapidly fatal to fishes.

Sulphur crystals may be obtained by dissolving sulphur in hot concentrated acetic acid, and evaporating the solution at ordinary temperature.

M. GAUTIER states that the tannin of Chinese galls is chemically distinct from that found in Aleppo galls.

States—an average of almost one postoffice to every 1,000 inhabitants, which speaks well for our public means of inter-communication, placer minings will foot up between \$25,000 and \$30,000. None but Chinese are engaged in this industry there.

river, a distance of about 35 miles from here, out of which a sufficient quantity of gold and silver ore has been extracted to give a good general idea of its merits; the result being as follows: Gold, per ton, \$5; silver, \$25; and copper, 7%.

KARVILLIUM IRON.—Harley & Co. are getting ready to put their mill, that stands on the east side of the river, in operation. The ore will be sent down to this mill from the Mineral Hill mine by means of a Wise tramway 14 miles long.

MARIPOSA.

Rich Strike.—*Gazette*, July 10: Wm. R. Carson & Co. have made a rich strike on Temperance creek, in Hunter's valley, near the old Oakes & Reese mine. This was formerly known as the Hammerstrand copper claim. They have taken out \$5,000 or \$6,000, and the mine still continues to pay handsomely.

MONO.

LAKE DISTRICT.—*Mammoth City Herald*, July 3: In the Mammoth main tunnel in No. 3 has been advanced 45 ft, making a total of 1,074 ft. The upraise from this level has extended 20 ft, making the total height about 60 ft. The mill started up to its full capacity on the 1st inst., with 40 stamps, the water machinery being run by water power alone, with supply sufficient to run the 40 stamps, 16 pans and 3 settlers, with quite a stream flowing through the waste ditch. The mill is crushing from 75 to 80 tons daily. There is an accumulation of about 400 tons of ore at the mill from tunnel No. 3.

H. L. & M. C. JOSEPHSON.—The hard character of the rock encountered during the past few weeks in this tunnel has given place within a day or two to a softer formation, and henceforward it is expected that better headway will be made. The ground is now drilling and breaking much better.

NOTES.—The Lisbon, Last Chance, Merrimac and other mines on the south of old Mineral Hill are fast turning out first-class gold mines, upon several of which there are rich strata. In a short time this short tunnel will strike the rich ore bodies for which it is run, and in all probability a mill will at once be erected on the property. Daily we hear of new finds being made in some of the old locations upon which assessment work is being done.

PAZCOST DISTRICT.—Jake Holsinger has shown us some rich specimens of rock from this district. The ledges from which the rock was taken are said to be large and of fine, easy access, with wood and water in the greatest abundance.

NOTE.—At the head of Bloody canyon Messrs. Hayt & Fuller discovered, last summer, some very large ledges of antimonial silver which assayed up in the hundreds, and upon which they intend doing work this season. Operations will also be commenced on several other claims by responsible parties.

NEVADA.

A NEW CLAIM.—*Transcript*, July 4: Messrs. Richards, Johns and Jenkins have started a mining tunnel on Deer creek, between the Merrimac and Mountaineer locations. They have been at work there for 5 or 6 weeks past, and are running for the same ledge on which the Spargo mine is located. They expect to strike it within a few ft further.

DERBEE CLAIM.—We learn from good authority that the Derbee has produced about \$15,000 worth of gold during the last month, and the gravel looks better than it has at any time since the mine was opened. The prospect of a dividend to the stockholders is very favorable at the present time.

EUREKA NO. 2.—There are about 100 tons of ore on the dump at the Eureka No. 2, situated on Little Deer creek, 3 of a mile east of this city. The 4-stamp mill has been running constantly till within a week, when it was shut down to admit of the ditch being cleaned. It will start crushing again Tuesday. The ledge, which has an average thickness of 12 ft, is worked by a tunnel, and pays from \$8 to \$8 per ton, besides the sulphurets.

NEVADA CITY MINE.—*Transcript*, July 9: This company is making arrangements to put 2 more Frue concentrators in the mill next week, when the full complement of 10 stamps will be started to crushing, the 5 now in use not being sufficient to dispose of the ore as fast as it comes out. Yesterday the 24 level produced some of the finest ore yet found in the mine. Several of the large specimens brought to town showed heavy streaks of free gold, besides a great deal of galena. There is probably not a very extensive deposit of such quartz in the mine, but what is found from time to time will likely pay at the rate of from \$20,000 to \$30,000 to the ton. The miners are taking out considerable sulphurets ore that is very rich.

LAKE VALLEY MINE.—For 3 years past, S. P. Dewey, of San Francisco, has had a force of men engaged in running a tunnel at Lovell hill, 15 miles east of this city, penetrating the hill a distance of about 1,000 ft. The expense of the prospecting done has not fallen short of \$30,000. A few days since an extensive deposit of gravel was found for the first time, and what is better, we are informed that it is very rich. The channel developed is the same one from which the Swamp Angel company has been realizing a heavy profit for 10 months past.

IDAHO.—*Grass Valley Union*, July 8: The yield of the Idaho for the month of June was \$41,500. The product of the mine has shown a marked increase in the last 3 or 4 months, and the appearance for the future is excellent.

PLACER.

CONRAD RICH ORE.—*Herald*, July 0: George Macombe has in his show-window a chunk of quartz rock less than a man's fist, from the Conrad mine, on Duncan hill, now being worked by the Messrs. Roberts, which is very rich in gold. It is estimated by some to contain over 3 ounces of gold. Mr. Macombe informs us that over \$700 worth of specimens from this same ledge has been sold to jewelers.

PLUMAS.

EALE OULON.—*Cor.* *Mountain*, July 3: The quartz mines at Eale Oulon district, near alternating public attention are all found on the Diadem ledge, a large ledge running through the center of the district, with a general direction of northwest and southeast, and a dip of about 60° to the northeast. The ledge is generally much decomposed, the veinstone being magnesian limestone, intersected by innumerable veins of quartz and by veins and masses of talcose rocks. The decomposition of the limestone has changed the ledge into a soft body of yellow and red material which generally contains free gold through its entire mass. The chief explorations on this ledge have been made in the claims of the Diadem mining company, in which the ledge formerly was covered by a gravel deposit, worked since 1854, and noted for its richness in coarse gold.

DIADYM.—Late last fall the owners of the Diadem found excellent prospects on the surface of the ledge, and early in the spring a short tunnel was run, striking the ledge at a depth of 25 ft. Adjoining the footwall a narrow body of quartz, mingled with talcose slate, was found of extraordinary richness, the lumps of ore in many instances being 1/2 gold, while next to this streak, soft quartz, averaging 2 ft in width and estimated to contain \$30 per ton, follows the direction of the footwall.

SIERRA.

SAVAGE PLACER.—*Mountain Messenger*, July 10: The tunnel has passed through the hard white rock (a mixture of quartz and granite) and entered a slate formation which is much softer. The recent rich strike in an adjoining claim was made at a point about 400 ft east of the east line of the Savage Placer, in what is supposed to be an overflow from the main channel that passes down through the ridge. At a proper point in the slate rock the Savage Placer folks will make an upraise to the gravel.

DOWNVILLE QUARTZ.—*Cor. Messenger*, July 10: Since my last I have found several new prospects; one a ledge 20 to 25 ft thick west of the main ledge, and on the east it will average 16 in. I think it will yield about \$8 per ton. The gold is fine and is chiefly in the sulphurets. As far as surface indications go, it is the most promising mine that was ever struck in this vicinity, and I think when this range is thoroughly prospected and opened for work, that it will be to Downville what the Buttes is to Sierra City.

TRINITY.

MONTE CRISTO MINE.—*Journal*, July 3: Some of the richest quartz in the State is now being found in Trinity county. One day this week Fred Diener founded up a pound and a half of rock from the Monte Cristo mine at Deadwood and obtained 2 ounces of gold, lacking only \$1.

TUOLUMNE.

CLIO MINE.—*Cor. Independent*, July 7: This claim is located on the mother lode, the same on which the Rawhide Ranch, Jamestown and Quartz Mountain mines are located. The mine is fitted up with a 10-stamp mill and other appliances for the reduction of ore. We understand that this is in the Eastern market.

NOTES.—Jim Diroll, in company with a number of enterprising quartz miners, are opening out a new vein near Stevens' ferry. They have already found some very flattering prospects. The quartz interest in this locality, like many other parts of the county, is assuming considerable shape, and is paving the way for a system of operations on a larger and more extensive scale than is seen at the present day.

WATERS MINE.—*Independent*, July 10: Sulphuret works are being constructed at the Waters mine, Tuttle town. It is expected the furnaces will be ready in about 3 weeks. The width of the vein is not known, as a cross-cut of 22 ft has not yet found the opposite wall. The ledge carries 15% of sulphurets right along, which yield from \$75 to \$85 per ton. The 10-stamp mill is a model piece of workmanship, and crushes, on an average, 19 tons in 24 hours.

NEVADA.

WASHOE DISTRICT.

SIERRA NEVADA.—*Gold Hill News*, July 10: On the 2400 level the north drift has been advanced 35 ft; total length, 980 ft. On the 2300 level the west drift has been advanced 16 ft; total length, 258 ft. At this point the drift was continued and the work of cutting out a chamber for an upraise commenced.

USAR CO'S DRAIN.—In being cut in the main south drift on the 2300 level. On the 2500 level the south drift has been extended 9 ft, the face showing quartz assaying from \$2 to \$20. The northeast drift from the Union shaft, on this level, has been extended 25 ft, and the south drift from the same point has been extended 30 ft.

MEXICAN.—On the 1000 level the joint Ophir east cross-cut has been extended 30 ft. On the 2300 level west cross-cut has been extended 14 ft. On the 2500 level the joint Ophir east cross-cut has been advanced 37 ft, and the north drift 55 ft.

ORINA.—On the 1000 level the joint Mexican east cross-cut has been extended 30 ft. On the 2000 level the main south drift is being cleaned out to the California line. On the 2500 level the north drift has been extended 10 ft, the joint Mexican east cross-cut 37 ft, and east cross-cut No. 1 9 ft.

HALE & NORCROSS.—Have sunk and timbered the incline 15 ft. No work has been done on the 2100 level. There are 243 tons of ore on hand; average assay, \$40.77.

BELCHER.—The north drift on the 3000 level has reached the Crown Point line, where it has been stopped. Connection will be made with it from the Crown Point side. The distance which the Crown Point east drift must be run to make the connection is 100 ft.

CALIFORNIA.—During the past week 243 tons of ore have been extracted and sent to the mills from the 1650 level. On the 2300 level the north drift has been extended 13 ft.

CON. VIRGINIA.—During the week there have been 600 tons of ore extracted and sent to the mills from the slopes on the 1750 level. On the 2000 level a chamber is being excavated for the joint Best & Belcher winze.

AURORA DISTRICT.

PROSPECTUS.—*Emerald Herald*, July 10: A contract was let Thursday to extend the tunnel to the footwall, calculated to be about 30 ft distant, making the ledge matter a width of 130 ft, all in paying ore. A contract was also let to extend the south drift several hundred ft on the main ledge. Good judges of ore estimate that the ore taken from this drift will not fall short of \$100 at the present time, and better ore will no doubt be found as the drift attains depth.

ROBERT ENNETT.—Yesterday a contract was let to extend the shaft 50 ft deeper. There is good ore in the shaft from top to bottom.

CENTENNIAL.—The work of extracting ore goes steadily on. Both shafts have out several tons of rock that will go away in the hundreds.

TUC. EMERALDA.—About 25 tons of first-class ore has already been extracted. Assays range from \$100 to \$1,000 per ton. The work of taking out ore will continue.

NORTHERN BELLE.—The shaft is now down 50 to 65 ft; sinking on the ledge. Rich ore from the top to the bottom. Several men will be put to work in a few days taking out ore.

GRAND FRANK.—This company has instructed Mr. McIntosh to let another contract to crosscut their ledge, and he expected to have to run 50 ft before striking it, but was agreeably surprised by finding quartz the first 3 ft run.

BRISTOL DISTRICT.

NOTES.—*Pioche Record*, July 3: The managers of the Bristol company are now pushing the work along rapidly at the mill site. The battery pans and settlers of the mill are already in position, and work of putting up the frame will commence next week. The sinking of the artesian well is progressing as usual. An important development has lately been made in the Hillside, on the 5th level east, which is very promising. The Hillside furnace is still in steady operation and working through a large amount of ore. Work has already commenced on the Mayflower mine of the Bristol S. M. Co.

CHERRY CREEK DISTRICT.

TEACUP AND GENEVA.—*White Pine News*, July 3: Prof. Herr, of New York, after examining the record of these mines, started for Cherry Creek, where he is to meet Prof. Newberry, and a sale of the mines will probably be made. Both of these mines have always been considered among the best in the district. The Teacup alone has produced over \$500,000. The new company will develop the mines on a large scale, and no doubt will before the end of the present season be more than reimbursed for their outlay.

COLUMBUS DISTRICT.

LUCKY HILL.—*True Fissure*, July 10: The winze is now down 160 ft, with favorable ground still in ledge matter. The crosscut south from the 110 level is in 30 ft, with the face in good ore. A hoisting engine for the winze has been purchased, and will be sent to the mill without delay. Mr. Baldy, who returned to San Francisco from Candelaria, pronounces the Lucky Hill prospect the most promising in the district.

NORTHERN BELLE.—There is no particular change in the mine, with the exception that a fine body of ore has been opened on the 9th level. It averages 3 ft in width. Both mills were again started up this afternoon and will run on full time.

SARAH JACOBSON.—The lightning incline crosscut southeast on the 150 level is in 35 ft and in good ore. Work on the silver incline has been discontinued until connection will be made by the crosscut from the lightning incline.

VICTOR.—Sinking is still progressing. The ledge in the bottom is 7 ft in width and still carries the same character of material as before. The windlass and derrick are now in position, being pushed ahead, and is now in 750 ft.

MOUNT PORT.—Nearly 400 tons of ore have been shipped to Belleville, and the ore-house there being filled, further shipments have been discontinued until milling begins.

NORTH NEW ENGLAND.—The ore improves as depth is attained, though not much work has been done in the bottom, owing to fitting up the mill. The shaft has been advanced 10 ft. The tunnel has now reached a distance of 113 ft. Some rich streaks of ore are now being cut, and in going 10 ft further it is expected the main ledge will be cut. The ledge croppings stand out boldly about 25 ft in height on the surface, the assays from which are very encouraging.

CAMPBELL DISTRICT.

NOTES.—*Silver State*, July 10: According to report the new mill in this district is temporarily shut down, owing to the fact that the ore is too base to work without being roasted, and an effort to concentrate it proved a failure. We understand that roasting furnaces are to be put up there at once, as the ore carries silver enough to pay well if it can be saved.

DUN GLEN DISTRICT.

LANG SYNE MINE.—*Silver State*, July 10: A note from Dun Glen informs us that the white miners at the Lang Syne mine have been supplanted by Chinese. Some white men who have been at work in the mine and have families in the camp, are said to be hard up for the necessities of life. It is greatly to be regretted that Chinese should be employed in any mine these days, when there is a glut of white labor in the market.

EUREKA DISTRICT.

REMY-HENDERBERG.—*Sentinel*, July 10: During the month of June, the Remy-Henderberg company shipped about 600 tons of ore to the Richmond works, which yielded some \$20,000. The mine still continues to look good and bright. The present month will probably make as good a showing as the last. All old encumbrances have been removed from the company's property, and we understand they have a very respectable bank account.

RICHMOND CO. This company yesterday commenced breaking ground for the erection of a new foundry. The immense amount of castings used by the company, and the great quantity of iron at their command, otherwise useless, has induced them to construct a foundry of their own. It will make a great saving to the company.

EUREKA CO'S.—*Official Letter*, July 3: The mine is looking well, with plenty of ore to run both furnaces. The ore-bins are all filled, both at the mine and furnaces. Have made better progress this week with the new shaft. Both furnaces are running smoothly, and producing the usual amount of bullion.

PHILADELPHIA DISTRICT.

BELMONT.—*Cor. Courier*, July 3: The drift started south from raise in north part of mine was advanced 14 ft during the past week through some rich ore. We started a drift going north from this raise, which is showing from 18 inches to 2 ft of ore; vein 4 ft thick. Our raise from end of west crosscut was advanced since last report 11 ft through vein matter and quartz. The ledge is getting more solid and free from slate as we advance, and I am in hopes of soon getting ore.

BELMONT.—*Official Letter*: Have made 15 ft in main tunnel. Ground solid and seams with small strata of quartz. On north upraise we have made 10 ft; ledge 4 ft solid, showing considerable cinnabar and sulphurets. In surface shaft to connect with upraise we have made 27 ft during the week. I have also started work again in north level.

PIOCHE DISTRICT.

DAY MINE.—*Record*, July 3: We visited this mine recently and found the dump and ore-house filled with high-grade ore, the assays averaging from \$116 to \$130 per ton. We should judge that there were about 200 tons of ore on the dump, and being piled up where a person can walk around and examine it, it naturally takes one's eye and looks very handsome. This ore is from the cave ore body. There has not been much change in the inside workings of the mine since last visit. The ore has always been found in pockets or chambers.

WILLOW CREEK DISTRICT.

ETHAN ALLEN.—*Paradise Reporter*, July 3: We learn from parties just over from Willow Creek that the incline on this mine is down a depth of 65 ft, and that the ledge at the foot shows a considerable amount of argentiferous galena and carbonate ore, assaying from \$45 to \$150 per ton in silver. A crosscut is now being run from the foot of the incline, and we hope in our next issue to be able to make a much more favorable report.

PAYSON.—This mine, from which we were shown some samples, is an extension of the famous Ohio mine, at Willow Creek. The samples shown us were very fine, and as the claim is being prospected by 2 shafts, we expect in a short time to chronicle another rich strike.

ARIZONA.

PATAGONIA DISTRICT.—*Tucson Citizen*, July 3: The Davis mine in this district is something more than a prospect. A prospect shaft was sunk to a depth of 35 ft, just above the cut which laid bare the immense body of ore on the surface. A drift was run east some 600 ft, which crosscuts the ore body full 40 ft in width. A cut was extended north 20 ft, most of the way in very rich ore. The south drift is in 60 ft, showing up very well. From this drift a winze was run down on the ledge in 35 ft of solid ore. This winze extends down 100 ft, where the 130 level has been run in some very fine ore, which assays \$100 in silver and runs fully 40% lead. The ore is remarkably free, and may be readily reduced.

MARK TWAIN.—This mine is near the Davis, and is prospecting fine. A crosscut was recently made in the prospect shaft, exposing a fine body of carbonate ore similar to that of Davis. These 2 mines belong to the Holland Co., of which Mr. J. K. Luttrell is the manager.

HARSHAW DISTRICT.—Work has been steadily prosecuted on the Julia, which lies about 1 1/2 miles from the town of Harshaw. A drift was run east about 25 ft, and discloses a 4-ft ledge of chloride ore. A pay streak 4 ft wide carries ore that it is believed will average \$30, as the rock is of a most uniform character, and assays as high as \$115 have been obtained.

NOTES.—The Delaware has a 30-ft tunnel all in ore, and the Brick Top, which joins the Delaware, has a 30-ft shaft in the vein, which carries ore all the way across. Assays from this fine ledge body run as high as \$175.

TOBACONIST DISTRICT.—*Nugget*, July 3: Work on the Bradshaw mining property is progressing, and the shaft, now between 90 and 100 ft in depth, is being heavily timbered from the bottom, preparatory to its becoming the working shaft. The large body of rich ore, some of the best in the district, which is seen from the top to the bottom of the shaft, is a sight well worth the trip to see.

VIRNA MINE. The developments in the working shaft of the Virna mine are of the most encouraging nature, the body of rich ore which has been reached, widening out and giving every evidence of being all in extent and permanency that the company could hope for.

NOTES.—A claim which has just had some work done on it by the owners, and which is now being worked by the Virna mine, has been developed some good ore at the bottom of a 20-ft shaft. The boisterous work on the Sulphuret mine steamed up this week for the first time, which now makes 7 in operation in the district and all near the town.

GLOBE DISTRICT.—*Cor. Silver Belt*, July 3: At the Mack Morris mine there are several hundred tons of ore on the dump, and the mine is constantly increasing from the winze, 30 ft deep, in the second level of the east shaft. The strike in the winze had been made the evening previous to our arrival, and consequently, all were jubilant, for the value of the ore was \$927, as was subsequently ascertained by assay.

NOTES.—G. W. Sharp has run 40-ft tunnel on the Cora mine, third extension west on the Mack Morris and Richmond, and has struck the main ledge, which shows a good prospect. The Victoria, adjoining the Richmond on the north, has a 12-ft shaft, which shows very rich ore. The Silver Nugget mill is now running on good ore. The Supt. assures us that he will turn out \$30,000 bullion within 30 days, or \$1,000 a day with 5 stamps.

PAYSON.—*Arizona Miner*, July 2: We are pleased to know that the Model mine, recently purchased by Gov. Powers, has commenced to send forth bullion. Six hundred dollars were brought in from the mine recently, which was secured by arastor process. When the Governor shall have erected his new stamp mill on the Model, bullion will go forth and the boom will have commenced.

COLORADO.

PARK COUNTY.—*Fairplay Flume*, July 3: Information reaches us of an excellent strike on the Chasapaign ledge, located near the headwaters of Mosquito creek. The miners who are at work driving the lower tunnel have recently been taking out very high grade mineral from a small vein that has been followed from the surface. The vein in the breast of the opening measures about a foot in width and assays from 650 to 2,500 ounces have been secured from specimens taken.

SURET MOUNTAIN.—The late strikes on this mountain are of such great importance as to attract hundreds of prospectors, and not a foot of ground remains vacant so far as is known. One venturesome prospector has pitched his tent on the very summit of the mountain and numbers of others are camped but a little lower down. On the Independence ledge an 8-inch streak of galena has been determined.

ALMA PLACER.—On these diggings 40 men are employed, a double shift being kept on continually, in order to make the best use of the water while it lasts. Three flumes are used in the hill diggings and the bed-rock flume is being pushed on up stream quite rapidly. The rate of wages paid is \$3.50 per day for a 12-hour shift.

CRABO MINE.—The vein in this mine is 14 ft thick, and a working test of 2 tons yielded about 325 per ton. Lately the assays run higher than usual, as three assays 60.73 and 120 ounces of silver, and from 60% to 73% of lead to the ton.

CLEAR CREEK COUNTRY.—*Colorado Miner*, July 3: The new strike in the Rip Van Winkle, which is situated near the summit of Snake River pass, toward Gray's Peak, is of great importance. At week 13 inches of solid ore were struck, and a number of assays were made which ran from 362 to 364 ounces. It has now widened out to 3 ft of quartz and mineral, and as depth is gained the quantity and quality of the ore increases.

ALBRO LODGE.—This is one of the most promising mines in this section. The owners are engaged in driving a tunnel to cut this shaft and thus drain it. In the bottom of this shaft they have a large body of high grade ore. The tunnel is now 300 ft. in, and there yet remains 125 to run. They have in connection with this ledge, a 12-stamp mill, and accordingly they treat their own ore.

SUMMIT COUNTY FREES.—*Cor. Georgetown Courier*, July 3: About 10 tons of ore are being shipped each week from the Shock mine to Denver. The ore vein of the mine is from 4 to 5 ft thick, and mills from 300 to 400 ounces in silver per ton, the ore being quartz carrying chloride of silver.

LAURENT.—This mine is the most famous in Breckenridge. From 15 to 30 tons of ore are shipped each week, which mills about 125 ounces in gold, 70 ounces in silver and from 40% to 60% in lead.

IDAHO.

BANNER DISTRICT.—*Herald*, July 2: Forty men are now employed by the Elmira Co., and on starting the mill the force will be considerably increased. The vein of black sulphuret ore, rich in silver and discovered near the Crown Point a week or two ago, has widened from 6 inches to 2 ft, and is as rich as ever.

SALMON RIVER DISTRICT.—*Yankee Fork Herald*, July 3: The Yankee Fork Gravel M. Co.'s ditch is progressing favorably, three-fourths of a mile being already completed. The ditch is 9 ft. in width at the top, 5 ft. on the bottom and 4 ft. deep. There are 57 men at work. The ditch was commenced the 17th of June, and they will be ready to start up the hydraulics by August 1st.

QUARTZBURG ITEMS.—A force of men is at work on the Iowa mine, and a tunnel is running to cut the vein at a depth of 250 ft. This mine has yielded some exceedingly rich ore, and it will be made to pay well as soon as everything is in proper shape.

GIBBONVILLE DISTRICT.—*Cor. Butte Miner*, June 30: Gibbonville is in Idaho, a short distance across the divide from the head of the Bitter Root, and on the direct route from Missoula to the Yankee Fork mines. This is both a quartz and a placer camp. To work the former we have a 4-stamp mill and 14 roasters, and are already commencing to work the latter. The mine is rich in silver, and assays from \$30 to \$100 per ton. Altogether about 30 lodes that will pay have already been opened.

MONTANA.

DEER LODGE COUNTY.—*Butte City Miner*, July 0: The Burnett mine continues to yield about 35 tons of free ore per diem without making any apparent impression on the reserves in sight. It is situated in a very favorable position on the slopes in the east level, where there is such a mammoth body exposed that it is considered unnecessary to explore the mine in other places. The Dexter mill has been running 4 months almost exclusively on Burnett ore, and for some time the stamps of the Centennial mill have been kept busy from the same property.

HIGH ONE.—This immense ledge continues to yield as much ore as the milling facilities of the company will allow them to crush. The slopes in the east level are looking well and seem to be inexhaustible.

NOTES.—The first, or 40 level running west, connected some time ago with the Tom Hane shaft, 200 ft. distant, and is now about 70 ft. on the other side. Stopping is actively progressing in several places and a considerable amount of base manganese ore is being daily hoisted to the surface.

PHILIPSBURG DISTRICT.—A very important strike and one which caused considerable excitement in Philipsburg, occurred several days ago in the Salmon mine, one of the Algonquin Co.'s properties. On one of the lower levels a large body of exceptionally rich ore carrying a profusion of native silver was discovered.

MINES OF THE ALTA MONTANA CO. are looking and producing very well. The large water-jacket furnace is running in good shape and producing bullion which is now averaging 300 ounces of silver per ton, and about \$70 gold. The new 35 ton smelter has not yet arrived. When it comes it will immediately be put in place, and then the capacity of the works will be more than doubled.

NEW MEXICO.

LAKE VALLEY DISTRICT.—*Grant County Herald*, July 3: Two tons of ore from this district was lately taken to the mill of the Mimbres company, where it was pulverized, spread out and sampled by quartering and re-weighing, when an assay was made which showed the fine result of 692 ounces to the ton. There are thousands of tons of ore lying on the surface that will run from 30 to 70 ounces in silver.

NEW DISCOVERY.—A new mineral discovery has been made about 4 miles northwest of Nicol's ranch, on the Upper Mimbres. Croppings assay from 30 to 60 ounces.

The discoverer named his first location Victoria. **GRANT AND VICTORIA DISTRICTS.**—*Chronicle*, July 1: These districts lie in the southeastern part of Grant county, and a large number of locations have already been made. We were to-day shown some specimens of ore from the claims of J. G. Crittenden and J. M. Casey, in Stone-wall district, that are pretty near the solid stuff. Mr. Crittenden has assays made from this ore that run as high as 300 ounces to the ton. Work on these mines, suspended on account of Indian troubles, will be resumed in a few days.

Origin and Classification of Ore Deposits.

In the *School of Mines Quarterly*, for March, 1880, Prof. J. S. Newberry has a valuable paper on the "Origin and Classification of Ore Deposits." The Professor groups the occurrence of metals in three classes, namely: 1st, superficial deposits; 2d, stratified deposits; 3d, unstratified deposits. The latter class embraces, with even other divisions, the occurrence of deposits in limestone, his account of which we give in full:

Chambers or Pockets in Limestone.

These chambers form the receptacles of ore in many countries; but nowhere else are such striking examples of this class of deposit as those found in our Western mining districts. From a study of these, I have been led to add them to the catalogue of forms of ore-deposit as a distinct and important addition to those given by other writers. The distinctive characters of these accumulations of ore in chambers and galleries has not been heretofore generally recognized, and a want of information in regard to their true nature has led to much litigation and heavy losses in mining. The best examples of chamber mines are the Eureka Con., Richmond, etc., of Eureka, Nevada; the Emma, Flagstaff, Kessler, etc., in Little Cottonwood district; and the Cave mine, near Frisco, Utah. All these mines are alike in this, that the ore is found more or less completely filling irregular chambers in limestone. Some of these ore bodies are of great size, and the aggregate product of these chamber mines is so great as to make it necessary to record this as one of the most important forms of metalliferous deposit. From the Potts chamber in the Eureka Con. mine, it is said that ore of the value of a million dollars was taken, while a still larger amount was produced from the great chamber of the Emma. The origin of these chamber deposits is, in my judgment, simply this: A stratum of limestone, more than usually soluble in atmospheric water, carrying carbonic acid—which dissolves all limestones—has at some time been honeycombed by chambers and galleries such as those which traverse the limestone plateau of Central Kentucky, of which the Mammoth cave is an example. Subsequently this rock has been broken through and upheaved by the subterranean forces which have disturbed all our important mining districts; and through the fissures then formed mineral solutions ascended, flowing into any receptacle opened to them. Where these fissures cut an insoluble rock, they became, when filled, simply fissure veins; but where a cavernous limestone was broken into, such caverns and galleries as were opened were more or less filled with ore. It has been suggested that the caves now holding ore were excavated by the metalliferous solution; but we find some of them entirely empty, with their sides incrustated with spar, and having all the characters of ordinary limestone caves, and even where the ore occurs, the walls of the cavity have the same character, are hard and unimpregnated with ore. Hence we must conclude that the chambers were formed, like modern caves, by surface water; and when the country was upheaved and the rock shattered, only part of them were opened, and that these received the solution and ore, while the unopened ones remained empty. The character of the ore contained in the chambers varies much, as it does in the fissure veins of our mining districts; and the solutions from which they were filled must have been different in the different localities where they occur. Argentiferous galena was evidently the most abundant ore deposited in the chambers, as it is elsewhere; but in some cases, this is associated with a large amount of iron sulphide, in others very little; while the ratio of gold to silver is inconstant, and the aggregate of both varies from nothing to several hundred dollars to the ton. The ores of Eureka run high in lead, contain much iron, and about \$70 in the precious metals, half gold, half silver. The ores of the Emma mine carried less iron, more lead, much more silver, less gold, and a little copper; while those of the Cave mine, at Frisco, contain no lead, much iron, a little copper, and are sometimes exceedingly rich in both silver and gold. In all the chamber mines yet worked in this country, the ore taken out is thoroughly oxidized; but in the deeper workings of some neighboring fissure veins, the soft, ochery ores of the chambers are found changed below into compact masses of galena and iron pyrites; the galena carrying the silver—the pyrites, the gold. Hence we may conclude that the ore originally deposited in the caves consisted of sulphides, and that, whenever these mines shall be worked below the water-level, ore of this character will be found. It should be said, however, that if the theory I have suggested of the formation of the limestone galleries and chambers is true, they will not be found to extend to so great a depth as the ore bodies of fissure veins, since the excavation of the limestone, if produced by atmospheric water, must be confined to the zone traversed by surface drainage. In a very dry and broken country, the line of permanent water-level may be very deep, as at Eureka, where the ore bodies extend and are oxidized to a depth of at least 1,400 ft. Such a condition of things could only exist in a very dry climate; but we have evidence that there have been great climatic changes in our western mining districts; according to King and Gilbert, two wet periods having been succeeded by two dry ones, the last prevailing now. We may therefore find chambers wrought in the limestone in a dry period below the present or normal water-level. The enormous production of gold and silver from the

chamber mines already worked proves the great importance and value of this class of deposits; and while we may predict that they will be found to be more superficial than true fissure veins, no limit can be fixed to the future yield of mines of this character, even though they should not be profitably worked below 1,500 ft. from the surface.

The General Interest in Mining.

One of the surest evidences of the increasing interest in mining enterprises is found in the space which is being given to articles treating of mining in periodicals, some of which are not usually open to the discussion of technical subjects. This increased interest was first seen in the daily newspapers, many of whom took the matter up in earnest and created departments of mining, managed with greater or less ability according to the skill of the editors and the needs of the paper. Of course, in case of the dailies, it is in most instances purely a business transaction, in which the diffusion of authentic news is of less importance than the acquirement of perquisites from the company to whom the mining department is shown to be a desirable medium for advertisement.

The same, however, cannot be said of the monthlies and quarterlies, which occupy an entirely different field from the newspapers, and which are far more conservative and independent in their opinions. Even here, however, the "boom" has made itself felt, and the literary conservatism of the former has in several cases fairly broken down under the stress of popular interest, and they have opened their columns to thorough-going and discriminative discussions upon the mineral resources of the country, and upon the methods and results of mining both in general and in particular. Two notable examples of this sort are found in the January number of the *British Quarterly* and in the April number of the *National Quarterly*. Last of all, the staid and conservative *Atlantic Monthly* joins the ranks with a well-written article in the June number upon the future of mining upon the American continent, by Prof. N. S. Shaler. Prof. Shaler's extensive knowledge as a practical geologist enables him to generalize in the matter with a good show of reason, and to draw some useful deductions as to the conditions under which deposits of gold and silver take place. With some of Prof. Shaler's theories we may not be able to agree entirely, but we find ourselves in full accord with him in his optimistic confidence in the vast increase of the mineral production of this country in the future, and we think that the arguments by which he supports his predictions are eminently sound and just. There never has been any question in our minds as to the advantages which will accrue to this country from the development of her mines of precious metals. In this her future is assured, and the pre-eminence she has acquired in the past, and now retains, will be as a drop compared to her coming prosperity, providing the natural evolution of our industries is not interfered with by injudicious and harmful legislation.—*The Economist*.

Silver in Europe.

When Germany became inflated with money and pride after the successful issue of the French war, and the enormous indemnity that flowed into her treasury vaults, she thought she was about to direct the course of the world in commerce and finance as well as in diplomacy. The diplomacy is a riddle yet unsolved; in finance she is receding from her hasty demonization of silver, and is anxious to resume bimetalism. France and the countries of the Latin union use both metals, and the balance in the Bank of France is enormous—\$163,000,000 in gold and over \$245,000,000 in silver. England is the representative of monometalism, which she is able to maintain by her peculiar monetary system and by the unflinching confidence which the people and the government have in the Bank of England's ability to meet every crisis. But this faith has been put to a severe strain upon various occasions and it may be over-stretched yet. The difficulty of a bimetallic system seems to be in the exact adjustment of the fluctuating relations of the two metals and maintaining their reciprocal par values. The tastes and habits of a people have something to do in matters of finance. The Germans miss the silver for which they have no substitute, and they have not gold enough for active business uses. In our own case we have not reached the point of inconvenience from the inequality of the two metals. The volume of greenbacks has been fixed by law, and there is no danger of paper inflation in the present temper of the public mind. If, however, the smaller notes were called in, this would have the effect of releasing silver for ordinary use, and so depleting Treasury accumulations. Some writers profess to anticipate trouble from the excess of silver in the hands of the government through the well-known law that the inferior currency drives away the superior. The theory is indisputable, but we are as yet in no danger of its immediate application. In the first place, the silver is in vault and not in circulation, the bankers declining to receive it on deposit; and for the purpose of legal tender its place is more than supplied by the greenback, which so long as it is convertible is a great convenience; meanwhile the government has a growing balance of cash in hand, for which uses will arise before the amount becomes oppressive.—*The Economist*.

The Yellow Jacket Pumps.

The stupendous pumping machinery of the Yellow Jacket mine is now regularly at work whenever there is a sufficient accumulation of water. This machinery is regarded as a remarkable triumph of mechanical skill, and we spare space for the following description of it from the *Territorial Enterprise*:

The Pumps.

There are, in all, in the shaft 13 pumps, the lowest one being at the 3000 level and the upper one well up toward the surface. To support the weight of the rod there are eight balance hobs, which hobs carry a total weight of about 240 tons of ballast. As these hobs have considerable leverage the weight of the pump rod, and all its belongings, may be set down as being, in round numbers, 300 tons.

The pumps are on an average something over 200 ft. apart and at each is a large water tank. By the motion of the rod the water is pumped from tank to tank until moved from the bottom to the top of the shaft. When the huge iron plunger of a pump descends into its harrel or cylinder it forces up the column a quantity of water (80 gallons), which is poured out into the tank of the next pump above, and as it ascends it draws into its harrel 80 gallons of water from the tank at which it stands. Thus the work goes on at all the pumps and tanks throughout the shaft.

The Pump Rod

Passes through stays that are placed across the compartment every 30 ft., thus preventing all vibration. These stays are merely sticks of timber placed on all four sides of the rod, thus forming a square hole through which it plays up and down. On the rod at these points are placed chafing boards. In some places these are hickory wood, while in others they are some softer wood faced with angle iron. On the stays are placed little cups containing grease, so arranged as to slowly flow out and keep the chafing boards properly lubricated.

Rod-Catchers

Are an attachment to prevent the rod falling down the shaft in case of it breaking at any point. There are in all six of these rod-catchers. They are merely huge blocks of wood securely bolted and banded to the rod. In case of the rod breaking it can only fall a very short distance, as these large blocks prevent its passing down through the stays. These great blocks and the heavy elbs of iron bolted along down the sides of the rod give it vast weight and a most ponderous appearance—the rod itself being formed of a stick of timber sixteen inches square.

The Balance Bobs.

To simplify the description, it may be said a balance hob is a long beam of wood or iron resting near the center on a fulcrum. On the outer end of this beam is a large wooden box capable of holding many tons of iron ballast, while at the inner end is a huge iron clevis, by means of which the bob is attached to the rod. This clevis is not fastened to the rod immediately at the end or nose of the bob, but reaches down and connects with the bob 10 or 12 ft. below. This method of fastening is necessary on account of the swinging or rocking motion of the bob, which describes part of the circumference of a circle, while the rod moves straight up and down. By adding to the main beam, above described, braces that start from near the ballast box at one end and near the nose of the bob at the other, running up until they meet in the shape of the letter A, you have a balance bob just about as it is seen in a mine.

The Pump Column

Is the large iron pipe through which the water is forced up out of the mine. At the Yellow Jacket this pipe or column is 14 inches in diameter. It is of wrought iron and very heavy. In order to support the column in the shaft there are large collars upon it at regular distances, which collars are supported upon the heavy timbers about the pumps and at other proper and convenient points. By this means the great weight of over 3,000 ft. of column is little felt at any one place.

Extra Pumps.

There are six pumps above the point where the south branch of the Suto tunnel will tap the shaft. When connection is made with the tunnel these may all be taken out and used at points below if necessary. The disconnection of so many pumps will greatly lighten the work of the engine and much relieve the strain on all parts of the machinery.

A Wonderful Feat.

The simultaneous starting up of a line of pumps 360 ft. over half a mile in length is truly a most remarkable achievement and a feat that has never before been performed or attempted in any part of the world. When the big engine made its first revolution all this half mile of pumps made a stroke. Not only was the whole pump rod of 300 tons moved but a great weight of water was also lifted. Had not every part of the rod, stays, hobs and pumps been in position almost to the breadth of a hair this could not have been done. Great credit is due Mr. Pyne, who placed in position all the 13 pumps, 8 hobs and the many other parts, for the patience, skill and excellent judgment displayed. A very little thing out of place at any one point would have caused a grand smash-up of everything.

Traction Engines on Hawaiian Sugar Plantations.

Mr. Williams, manager of the Kohala plantation, writes the following account of experiences with three English traction engines; one of 10-horse power and two of 8-horse power each. He says:

To-day is the fourth week that I have not had a bullock team hauling cane. Two engines with four cars to each engine (2 small and 2 large) were hauling from one field $1\frac{1}{2}$ miles away, 6 trips a day; and one field near by, 9 trips a day, all ratoon cane, and are taking 23 clarifiers a day (with cattle we could only get cane enough for 21 a day). To get in this amount of cane would take 15 of our cane wagons, with five yoke of cattle to each team. We go right into the field close to the cane, just as we do with cattle, and can dump the cane closer to the cane carrier than we can with cattle.

Have been keeping account of coal used on each engine for three weeks full work every day, and find we have used about 51 or 52 tubs a week on each engine. A tub weighs on an average 80 lbs. of coal, so 4,160 lbs., say to estimate 2 tons to each engine per week. I get in this amount of cane with 10 less men than if I had teams on. We have a driver (white man) and a native helper on each engine, and one native to walk alongside of the load and pick up cane that falls off, and help connect and disconnect in field and in mill.

Each engine has four wagons, two are loading in the field while the other two are being hauled in. There is no waiting in the morning till you get the cattle in and yoked up; the native helper gets his 20 cents overtime in the morning for getting up team before the whistle blows to go to work.

Directly the mill starts, the engine starts out to the field; the wagons are left loaded in field over night. She takes out her two empty wagons and brings in the full ones, dump them, and if it is breakfast time, they go to eat. They leave the engine standing alongside the road, it is all right, no team will blow off. We fetch in every trip equal to 4 of our large bullock wagons, (but this is with one large and one small wagon); with all English wagons we fetch in equal to 5 of our large bullock wagons at a trip. The other week we had two English wagons left loaded in the field at night; it rained heavily for the next two or three days, and being afraid the cane might sour, sent out some teams to unload them and fetch in the cane; it was as much as they could do to get the two onto five of our bullock wagons. As they did not know at the time they loaded the engine wagons, we call it a fair test. This is on ratoon cane, if on plant cane we can load more, as the ratooners are shorter than plant, so cannot keep as much cane on a load. Some two years ago, to give Mr. Watson exact figures, I weighed 10 wagons of ratoon and it made 52,350 lbs. cane; so I calculate that with all large wagons we haul in at each trip 10½ tons of ratooners, and 11 tons weight of plant cane.

On one road where we are hauling, we come up a hill with a rise of 1 ft. to 11 ft. 3 inches; coming up a hill they put on slow speed at about $2\frac{1}{2}$ or 3 miles an hour; on level ground they put on their fast speed at $\frac{5}{8}$ or 6 miles per hour. The changing speed is done in half a minute, stop and change a pin in or out.

At mill the engine itself pulls off the load. We lay three ropes in bottom of wagon, made fast on side to bolts inside before loading. These ropes are about 50 ft. long each. When they get to mill we let down one side of wagon, throw the three ropes over the load and make them fast; we have a snatch block and tackle made fast to cane carrier, hook the tackle onto the ropes, lead the end of tackle to engine; it unhook from the wagons and walks off with the fall, pulling off all the cane. Before we got hold of this method, we used to have to stop the mill and put on 30 hands to pull on the ropes to pull the load off.

As far as I can estimate at present, charging \$5 per day for driver, the cost of native helpers, loaders in the fields, coal, oil, etc., 10% on cost of engines, and allowing for wear and tear, what costs us at the rate of \$90 per day with cattle, we haul in with traction engines for \$60 a day. In the \$90 for cattle, the rent of pasture lands and miles of fencing and keeping is not included, which is a large item, when a great deal of your pasturage will do for cane. You cannot work the engines in wet, showery weather, and they will have to be worked up into a system. They more than come up to my expectations. In fine weather, when it is hot and dry, and your cattle play out, is the time for the engines and the time to push your grinding.

CENSUS OF NEW YORK CITY.—The census returns for this city are now so well in hand that the total can be given with considerable precision. The population of the metropolis is 1,207,215. This marks a gain of 254,923 in 10 years, and of 1,004,626 since 1830. In a quarter of a century the population of the city has doubled. At the same time all the metropolitan suburbs have increased and multiplied until New York as a center of population ranks next to London. Brooklyn, with a population of over 560,000, retains its place as the third city in the Union, although it can scarcely expect to keep it in view of the astonishing growth of the great cities of the West. Whenever the supremacy of New York as the metropolis of the country is seriously menaced, the annexation of Brooklyn will give it breathing space for at least one generation.

Mineral Resources of Southern Russia.

An important concession has been made to an American capitalist, Mr. Wharton Barker, by the Russian government, to undertake, under very favorable conditions, the development of the mineral resources of southern Russia, with particular reference to the coal and iron fields bordering upon the Sea of Azof, which are believed to be immense. A commission of geological experts has visited the region and made a very favorable report of the magnitude and possible value of the mineral riches of the country; and, on the strength of this report, a body of railway and manufacturing experts, in the interest of leading American capitalists, has set out for the purpose of estimating the commercial value of the proposed enterprise.

The project that is being set on foot will, if undertaken, prove to be the greatest enterprise ever entered into between American capitalists and a foreign power. Should this preliminary investigations now making be quite satisfactory, the work will be undertaken at once. It is understood that the concession granted by the Russian authorities includes the exclusive right of opening up the Donetz coal-fields, north of the Sea of Azof; the iron deposits of Krevoi Rog, north of the Crimea; the construction of a railway system in connection with these developments; the establishment of a great shipping port on that sea; the erection of Bessemer steel works, grain elevators, etc. To realize this ambitious project, it has been given out that \$5,000,000 will be required, and this amount is said to have already been pledged by New York and Philadelphia capitalists, contingent upon this satisfactory outcome of the preliminary investigations now in progress.

LUMINOUS PAINT NOT NEW.—Much is being said, just at this time, in regard to the utility and novelty of a luminous paint recently invented by Mr. Balmain. But now comes *Nature*, of June 10th, and informs us that the Japanese were acquainted with the art of luminous painting 900 years ago. That publication gives a translation from a Chinese book, written about that time, from which it appears that one Su Ngoh had a Japanese picture of an ox, which, it was said, left the frame every day to graze, and returned every night to sleep within it. This picture finally came into the possession of one of the Chinese emperors, who showed it to his courtiers, and asked for an explanation, which none of them could give. At last a Buddhist priest informed the emperor that the Japanese found a substance in a certain kind of oyster, out of which they manufactured a paint which was invisible by day, but luminous by night. The explanation was given by the writer of the book, that when it was said the ox left the picture by day to go a-grazing, it was simply understood that during the day-time the figure was invisible.

CHINESE SHIP-BUILDERS.—It has been something of a mystery to Americans in the light of the remarkable depression of the carrying trade in the recent years, that British ship-builders should continue to turn out so many iron steamships. A convention of American ship owners has been proposed, to be held next October, with the view of agreeing, if possible, upon what legislation is required to place our merchant marines upon a basis that will enable it to compete successfully for ocean commerce. But the seeming mystery is largely explained by the fact that a firm of Scotch ship-builders are said to have established themselves at Shanghai, and are turning out iron steamers of the largest size. All of their 1,100 workmen are Chinese, who labor for a few cents each per day. Notwithstanding nearly all the raw material used in those yards has to cross oceans, nowhere in the world can a ship be built more cheaply. The *London Times* sees in this fact something seriously ominous to the shipwrights on the Clyde and the Tyne.

THE LARGEST HAILSTONES.—It has hitherto been supposed that the report of the *Bombay Gazette*, quoted in *London Nature*, of a hail-storm occurring last March at Dharwar, during which hailstones fell that measured 9 or 10 inches in circumference, was the most remarkable case on record. It has since appeared, however, on the authority of the *Iowa Weather Service Bulletin*, that during the month of April, 1880, thunder-storms occurred in that State, during which hailstones fell measuring 12 inches in circumference.

A NEW SKATING SURFACE.—A skating surface, called by its inventor, "crystal ice," has been laid down in a London skating rink. It consists of a mixture of the carbonate and sulphate of soda. The crystallization of these salts produces a floor which so closely resembles ice, both in appearance and the resistance of its surface, that when it is a little "cut up" the deception is said to be quite astonishing. It can be skated on with ordinary ice skates. When roughened too much it is smoothed away by steaming with an apparatus provided for the purpose.

AN AMERICAN SCIENTIST HONORED.—At Berlin recently the prizes to exhibitors at the International Fishery exhibition were distributed. The first honorary prize was awarded to Prof. Baird, of the Smithsonian Institute, United States. He will receive a gold medal and an address. At the distribution of the prizes Prof. Baird, of the Smithsonian Institute, spoke, eulogizing Emperor William, who, he said, was to be found in every place where there is an opportunity for promoting goodness and truth.

USEFUL INFORMATION.

How to Use Glue.

The following practical hints on the preparation and use of glue are from the *London Furniture Gazette*:

All the glue as received from the factory requires the addition of water before it will melt properly, and every addition of water (while the glue is fresh made) will, up to a certain point, increase the adhesiveness and elasticity; and it is the duty of every man who uses glue to find out just where that point lies, as it is possible to melt glue and have it so thick that after it is dry or set it will be so brittle as not to adhere to the wood. Some glues will bear more water than others, but all will bear more water than usually falls to their share, and that, too, with a greater increase in the quality of the work.

For glue to be properly effective, it requires to penetrate the pores of the wood, and thus more a body of glue penetrates the wood the more substantial the joint will remain. Glues that take the longest to dry are to be preferred to those that dry quick, the slow-drying glues being always the strongest, other things being equal.

For general use, no method gives so good results as the following: Break the glue up small, put into an iron kettle, cover the glue with water and allow it to soak 12 hours; after soaking, boil until done. Then pour it into an air-tight box; leave the cover off until cold, then cover up tight. As glue is required, cut out a portion and melt in this usual way. Expose no more of the made glue to the atmosphere for any length of time than is necessary, as the atmosphere is very destructive to made glue.

Never heat made glue in a pot that is subjected to the direct heat of the fire or a lamp. All such methods of heating glue cannot be condemned in terms too severe.

Do not use thick glue for joints or veneering. In all cases work it well into the wood in a similar manner to what painters do with paint. Glue both surfaces of your work, excepting in the case of veneering. Never glue upon hot wood, or use hot cane to veneer with, as the hot wood will absorb all the water in the glue too suddenly, and leave only a very little residue, with no adhesive power in it.

A "Filler" or Polish for Wood.

(1.) Four parts of white wax are added to 3 parts of oil of turpentine, and the whole is heated in a flask or bottle, immersed in hot water, until the wax is liquefied and almost dissolved. It is then allowed to cool, and when it begins to turn white and to harden 2 parts of strong alcohol are added, under stirring. This mixture is applied by means of a woolen cloth and thorough friction. The alcohol may be increased to 4 parts, but the friction must then be continued for a longer time.

(2.) One pint of linseed oil, together with 2½ oz. of alkanet root, are heated to boiling in a clean pot over a slow fire, and kept at a gentle boil for about two hours. When cool, the mixture is applied in a thin layer to the wood, and after the lapse of 24 hours well rubbed in.

(3.) The best polish, particularly for fine wood, is milk! After all dust and dirt have been carefully removed, good fresh milk is applied to the wood and well rubbed in with a woolen rag, until all moisture has disappeared. This must be repeated several times, and in the case of new utensils should be done once a week. Milk has this advantage that its fatty substance answers the same purpose as linseed oil, and its other constituents act as a filler while it leaves no disagreeable flavor. For some light-colored woods sublimed sulphur with hoiled oil makes very good filling.

One ingredient, however, is necessary in all of the above processes, without which success will not be attained, and that ingredient is *adeps cubitalis*, vulgo "elbow-grease."

THE ABSORBING POWER OF EARTH.—Without obtaining a practical test one can hardly appreciate the absorbing power of dry earth, or the leaching effect of some kinds of soils. A writer says: "We once deepened a manure pit that had a blue clay bottom. This pit had been used for years, there was never less than a foot of water in it. After emptying we commenced to deepen it, expecting to find a rich black earth for a foot or two, but to our astonishment, the clay two inches below the bottom was not soiled, but looked as pure and blue as it did two feet deeper. But all kinds of soils are not as impenetrable to liquids as blue clay. By actual experience we have found that dust an inch thick over a dead animal will prevent the escape of bad smells. In hen-houses the effect is magical, preventing not only bad odors, but vermin as well. Even for old running sores and ulcerated wounds when chemical disinfectants could not be had, dry earth or dust has proved highly beneficial. The fact seems to be that neither the liquids nor gases of decaying matter can pass through two inches of earth without losing the greater part of what constitutes its peculiar characteristics, that is, its offensive or valuable portion, as the case may be. Properly used in the stables, cesspools, sink-drains, etc., dry earth will save a vast amount of valuable fertilizing matter, and prevent expensive and life-destroying disease."

A NEW SKATING SURFACE.—An English inventor, after much study and experiment, has, quite recently, devised an entirely new skating surface, which he calls "crystal ice," and which consists of a mixture of various salts, mostly, however, sulphate of soda, which crystallize at ordinary temperatures. This preparation, which is comparatively cheap, is simply spread out, in a plastic condition, from an excess of water, upon an ordinary floor. As soon as the excess of water evaporates the substance becomes crystallized, presenting a surface much resembling ice, quite as hard, and upon which ordinary ice-skates may be used with about equal facility as upon a water-frozen surface. When "cut up" by skaters, its surface can be readily smoothed by a steaming apparatus, and the floor, when once laid, will last for years. It is obvious that such a floor must have many advantages over artificial ice and floors for roller-skating. It is said that the mixture of salts used contains about 60% of water of crystallization; hence, after all, this floor consists mostly of solidified water. The above facts are obtained from *Nature*, of June 5th, in which it is further stated that a small experimental floor has proved such a complete success that a large skating rink is to be immediately constructed upon this principle.

WORCESTERSHIRE SAUCE.—The *Canadian Pharmaceutical Journal* says that the following recipe gives a sauce closely resembling "Worcestershire." Vinegar, 1 qt.; allspice, powdered, 2 drams; cloves, powdered, 1 dram; black pepper, powdered, 1 dram; mustard, powdered, 2 oz.; ginger, powdered, 1 dram; salt, 2 oz.; shallots, 2 oz.; sugar, 8 oz.; tamarinds, 4 oz.; sherry, 1 pt.; curry powder, 1 oz.; cayenne, 1 dram. Mix all the ingredients together, simmer them for an hour, and strain. A little brandy coloring may be added to darken the sauce.

TO CLARIFY LIQUIDS.—The following composition is said to bleach all colored liquids, and to render bone-black unnecessary: Albumen, 300 parts; neutral tartrate of potash, 2 parts; alum, 5 parts; acid ammoniac, 700. The albumen must of course not be coagulated. The ingredients are first dissolved in a little water, and then added to the liquid to be clarified.

A SURE AND SAFE RAT POISON.—The following mixture is sure death to the rats, and not poisonous to other animals, in the ordinary sense of the word: Take of old cheese 10 parts; glycerine, 2 parts; carbonate of haryta, 5 parts; rye or corn flour, 1 part, and form into pills or boluses of convenient size.

GOOD HEALTH.

Keep Your Mouth Shut.

The peculiar arrangement of the narrowed and branched and delicately-furnished nasal passage are specially suited to strain the air and to warm it before it enters the lungs. The foul air and sickening effluvia which one meets in a day's travel through the crowded city are breathed with greater impunity through the nose than through the mouth. Raw air, inhaled through the mouth, induces hoarseness, coughs, etc.

The great actor Cooke, when dying, told his friend and faithful attendant, Broster, that, although he could make him no bequest in money, he would give him something worth money. He then advised Broster to set up as a teacher of elocution, and to impart to his pupils, on condition of a large fee, and a solemn promise not to divulge it, the secret of his (Cooke's) extraordinary powers of voice and its unflagging quality, which was to carry on respiration through the nostrils, so as not to dry or irritate the delicate organs of the voice. Broster took this advice, and used it so well as to retire with a fortune. He made every young clergyman, who took lessons, sign a bond that in the event of his becoming a bishop he would pay a further fee of 100 guineas. John Thelwell inherited the secret from Broster, and used it with similar reserve and profit; but his son, on being appointed a college lecturer on public reading and speaking, disclosed the secret to all his pupils as a thing of the greatest importance to them.

Mr. Pitman gives an epitome of the experience of George Catlin in his travels among the Indians, of whom he visited 150 tribes. Everywhere he found the Indian women careful to press together the lips of their children after leaving the breast and before being suspended in their narrow cradles in the open air, and he found it to be a very rare thing to hear of a death during childhood among any of the tribes, before strong drinks and new diseases were introduced among them by the whites. It is said that no animal but man sleeps with his mouth open, and that the lungs need a degree of rest from labor which they get with the moderate inhalation that, with a slow puls, attends perfect nightly repose.

Mr. Catlin attributes his escape from malarial fevers, and his actual recovery from pulmonary weakness, to a strict observance of the rule to keep the lips and teeth tightly shut. When he went to the wilderness he was feeble. He found himself compelled to sleep in the open, dewy air. His one main precaution secured the entire restoration of his health and vigor. He found that all the Indians had good teeth, which

remained sound to old age, and that there were no stutters among them.

In his closing paragraphs he advises that mothers at home, and teachers in seminaries, should make nightly rounds as long as necessary to put a stop to the unnatural, dangerous and disgusting habit of sleeping with the mouth open. "No one who has been snoring through the night feels properly refreshed in the morning. Keep your mouth shut, my young readers—when you read silently, when you write, when you listen, when you are in pain, when you are walking or riding and by all means when you are angry."

MEDICAL USES OF EGGS.—For burus or scalds nothing is more soothing than the white of an egg, which may be poured over the wound. It is softer, as a varnish for a burn, than collodion, and, being always at hand, can be applied immediately. It is also more cooling than the "sweet oil and cotton," which was formerly supposed to be the surest application to allay the smarting pain. It is the contact with the air which gives the extreme discomfort experienced from ordinary accidents of this kind, and anything which excludes air and prevents inflammation is the thing to be at once applied. The egg is also considered one of the best remedies for dysentery. Beaten up slightly, with or without sugar, and swallowed at a gulp, it tends, by its emollient qualities, to lessen the inflammation of the stomach and intestines, and, by forming a transient coating on those organs, to enable nature to resume her healthful sway over the deceased body. Two, or at most three, eggs per day would be all that is required in ordinary cases; and, since the egg is not merely a medicine, but food as well, the lighter the diet otherwise, and the quieter the patient is kept, the more certain and rapid is the recovery.

The hair is much abused in its relations to healthfulness and growth. Pulled, twisted, torn, burned into a friz, and besmeared by all sorts of unguents and lotions, it is a wonder that baldness is not really the rule instead of the exception among those who most prize its beauty—the female sex. And it is equally neglected, if not abused, by most physicians, many of whom, while heartily condemning the thousand and one preparations well known to be not only injurious to the hair, but dangerous to the general health, show their total neglect on this part of their cure by relinquishing it to barbers and quacks. The treatise before us admirably fills a long-tolerated gap in the literature of the subject, which should not only be welcome to all physicians for whom it is a scientific treatise, while for the general reader it is also an entertaining work on the manners and customs of dressing the hair by all nations in all ages.

OAT MEAL FOR BREAKFAST.—In the last five years the consumption of oat meal in this country has probably increased 20-fold. People differ so much in their likes and dislikes that we do not insist upon anybody eating oat meal because somebody else does, but the great growth of the popularity is beyond doubt. Generally the Irish and Scotch meal have been considered best, but they sell comparatively high, and persons well acquainted with the subject say that Akron meal of Ohio is just as good. Oat meal should be well cooked. As it is usually made a breakfast dish, it may be soaked over night, and then boiled like mush for, say, half an hour, while the other part of the breakfast is getting ready. No doubt it is more wholesome eaten plain, but the temptation to use various "dressings"—generally cream and sugar—is too strong for any except very firm health-seekers. But where these are eaten it should be, as the friends say, "in moderation."

CONDITIONS INJURIOUS TO SIGHT IN SCHOOL CHILDREN.—Prof. Raux mentions the following: Air vitiated by animal emanations, vegetable or mineral dust, the smoke of various combustibles, especially tobacco, in which nicotine exists. Temperature too high or too low, and sudden changes or drafts. Clothing too tight, particularly at the neck or waist. Position with the head and body too much bent forward during labor with the eyes. Premature study, excess of reading, etc. Alcoholic excesses. Use of the eyes and brain immediately after eating. Habitual constipation, cold feet, and everything which tends to produce congestion of the head. Immorality, especially during childhood and youth. We might assign a cause still more potent than any of the foregoing, viz: a deficiency of light.—*Detroit Lancet*.

RAPID CURE FOR COLDS.—An Italian medical paper contains a letter from Dr. R. Rudolf, recording the discovery of a rapid cure for colds. Being seized with a severe coryza, he happened to chew one or two twigs of the eucalyptus, at the same time swallowing the saliva secreted, which had a bitter and aromatic flavor. To his surprise he found that in the course of half an hour the nasal catarrh had disappeared. Some days later he was seized with another attack, from a fresh exposure to cold, when the same treatment was successful.

WHEATMEAL OR OATMEAL.—Both these cereals are sufficient food for man. Oatmeal, however, contains more carbon, starch, or heat-producing material. Cornmeal contains a much larger proportion salt, while its albuminous constituents are greatly inferior to those of oatmeal; and wheatmeal, in its turn, is inferior to oatmeal in the same important constituents.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Hoover Telephone; More Thoroughness Wanted; The Outlook on the Comstock, 33. The Week; Vital Importance of Sanitary Regulations; Ore Crushing—No. 3, 40. Ruins at Aztec Springs, in Southwestern Colorado; Void Entries of Public Lands; Mining Operation in Idaho; Letter from the Comstock—No. 3, 41. Notices of Recent Patents, 44.

ILLUSTRATIONS.—The Hoover Telephone, 33. Ruins at "Aztec Spring," Southwestern Colorado, 41.

CORRESPONDENCE.—Notes from Plumas County No. 1; Notes from Shasta County, 34.

MISCELLANEOUS.—A Great Gravel Deposit; The Freeland Quartz Mine; Congressional Wisdom; Low-Grade Ores of the Comstock; How our Forests Disappear, 34. Origin and Classification of Ore Deposits; The General Interest in Mining; Silver in Europe; The Yellow Jacket Pump; Traction Engines on Hawaiian Sugar Plantations; Census of New York City, 38. Mineral Resources of Southern Russia; Luminous Paint not New; Chinese Ship-Builders, 39. Our Abnormal Gold Coinage; Reporting by Telephone; The Mongolian Mines; Demand for Gas Engines, 42.

MECHANICAL PROGRESS.—Improved Flour-Mill Machinery; Railroad Car Wheels; American Plate Glass; A "Prolograph," 35.

SCIENTIFIC PROGRESS.—Lighting and Oil Tanks; New Methods of Using Volatile Disinfectants; Progress of Electric Lighting Abroad; Thin Rolled Iron for Scientific Purposes; A New Nebula and a Lost Planet; Artificial Vanilla; Glycerine Cement, 35.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards; Notices of Assessments, Meetings and Dividends, 36.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana and New Mexico, 36-37.

USEFUL INFORMATION.—How to Use Glue; A "Filler" or Polish for Wood; The Absorbing Power of Earth; A New Skating Surface; Worcestershire Sauce; To Clarify Liquids; A Sure and Safe Rat Poison, 39.

GOOD HEALTH.—Keep Your Mouth Shut; Medicinal Uses of Eggs; The Hair; Oat Meal for Breakfast; Conditions Injurious to Sight in School Children; Rapid Cure for Colds; Wheatmeal or Oatmeal, 39.

The Week.

We are now in the full enjoyment of summer weather, which is agreeably cool and invigorating. In the interior the temperature is higher and more uniform, but it is pleasant and bracing, and both the farmer and the miner carry on their work with their accustomed vigor. This peculiar climate of our California, with its occasional blows and sudden changes, its quickly passing wavelets of heat and cold, is a priceless gift which we scarcely appreciate. Could the cool winds which blow over our city, and fill one's eyes with rubbish, pass for a day through the suffocating streets of blazing New York, they would be pronounced blessed by a million grateful hearts.

On Wednesday, the 14th inst., the French residents of this city celebrated the anniversary of the fall of the Bastille in a very spirited manner. All their business houses were closed, and their residences and hotels were decorated richly with the national taste. The procession, in which they were joined by a detachment of Swiss residents, was excellent, and attracted an immense concourse of sympathizing spectators. In the evening at the Grand Opera House orations were delivered in English and French.

An important feature has been added to the business of the stock exchange. Hereafter all our local securities, such as the shares of gas, water, bank, insurance, railroad, powder and other companies, and National, State and county bonds, will be called daily at a short session held just prior to the informal session. Under this new rule the first call of these securities was made on Wednesday, the 19th inst.

Business in the city is generally quiet, and is likely to continue so for several weeks. After that the incoming crops will make it lively enough.

The Central Pacific Railroad Co. last month carried 2,840 passengers East and 3,100 West, making a total of 5,940.

Vital Importance of Sanitary Regulations.

Huxley, in his Lay Sermon devoted to the "Advisableness of improving Natural Knowledge," directs the attention of his readers to this deadly plague by which London was smitten in the memorable years of 1664-5; when "death, with every accompaniment of pain and terror, stalked through the narrow streets of old London, and changed their busy hum into a silence broken only by the wailing of the mourners of 50,000 dead." And the learned preacher enforces the lesson that the dire experience of mankind has always taught that the condition of health and life depends on the knowledge and observance of natural laws. Men are "learning that pestilences will only take up their abode among those who have prepared unwashed and ungarmented residences for them. Their cities must have narrow, unwashed streets, foul with accumulated garbage. Their houses must be ill-drained, ill-lighted, ill-ventilated. Their people must be ill-washed, ill-fed, ill-clothed. The London of 1665 was such a city. This city of the East, where plague and cholera have an enduring dwelling, are such cities. We in later times have learned somewhat of nature, and partly obey her; but because that knowledge is still very imperfect and that obedience still incomplete, typhus is our companion and cholera our occasional visitor." While it is true that London, with its teeming millions, is to-day freer from causes of fatal sickness than it was during the time of Milton, its sanitary regulations based on known natural laws are so incomplete as to be appalling. Just think of this condition of things existing in the foremost city of the world! Mr. Torrens, M. P., in treating in the *Macmillan Magazine* of the water supply of London, says that even in the Mansion House itself (as an instance of what occurs in in-door cisterns in the houses of the wealthy) the cistern "was found to contain three-quarters of an inch of fungi scrub at the top, and three-eighths of an inch of mud at the bottom," while "in a bottle of water on the Lord Mayor's table could be seen hundreds of nematoid worms." From cisterns thus situated "probably nearly one-third of the inhabitants of London obtain their only stock of drinking water; and when we reflect on the liability of water to absorb germs and ferments without actual contact, and to become putrid, under certain conditions, in a few hours, we can hardly escape a shudder."

We are unhappily only too familiar with the melancholy history of fever-stricken Memphis, where the yellow fever had come to appear as certainly as the return of the season. She was in many degrees just such a city to welcome pestilence as the pen of the master has described. Her late experience in the terrible loss of 15,000 lives, and of an incalculable sum in money, was a tremendous penalty for the disregard of natural laws. But Memphis has learned her costly lessons in the bitter school of experience, and has at last bravely attempted to cure and prevent the supreme evil which has afflicted her. She has put her own shoulders to the wheel to lift it out of the mud. She has adopted a perfect system of drainage and sewerage and water supply, and general sanitary regulations which are both intelligent and practicable. And now the Memphis *Appeal* boasts with a just pride that "it is the only subsoil-drained city in the world;" and that from "being wet and boggy, the soil has become dry and healthful; and from being the most unsanitary city, Memphis has become the most thoroughly clean and sanitary city on the continent." The coet of these improvements has been vast, but they will be found to be infinitely cheaper than one year's visitation of the fever.

Perhaps the most remarkable example of the woeful disregard of the simplest natural laws occurred recently at Princeton College—an institution especially founded for "increasing God's honor and bettering man's estate." An outbreak of malarial fever in the college building prostrated some 40 of the students, and has already caused eight deaths. This unlooked-for disaster has excited general discussion.

The history of the outbreak of the pestilential fever goes back a little more than a month. Prior to that time there had been the usual sickness in college, but the simultaneous prostration of seven of the students drew special attention to the fact and led to investigation. An analysis of all the wells from which the students drank was ordered, and the result was that the water in a dozen of the wells was found to be impure. The investigation begun by the faculty of the college has revealed a frightful condition of affairs. Several years ago water-closets were put into all the dormitories on the ground floor, while sinks were placed in each hallway for lavatory purposes mainly. The water came from a pure spring. The sewage was carried off in a 12-inch pipe across the college grounds to a large cesspool having an overflow pipe at one end. Neither sewer nor cesspool had any adequate ventilation. The investigation disclosed the appalling facts that the cesspool had never been cleaned and was full to the brim, and that the sewer was more or less choked by the hacking of the deposit. The drains from all of the dormitories connected with this cesspool. In most of the college buildings there was absolutely no har to the noxious gases in the sewer and cesspool from entering the bedrooms of the luckless students. The tainted atmosphere had become specially

offensive, and still the poison was permitted to do its work. The interposition of sickness and death at last aroused the college authorities to the shocking sanitary condition of the buildings, and they have at last sought the advice of scientific experts in order to correct their glaringly defective drainage. At the late commencement of the college, Pres. McCosh, who is both a good and learned man, in referring to this death by malarial poison of the eight students, asserted that the calamity was "a dispensation sent to chasten and humble us." This remarkable assertion was made with the full knowledge that the improvidences of the college authorities was alone responsible for the criminal negligence of the simplest sanitary provisions by which the college buildings were converted into breeders of filth-diseases. In the words of an acute thinker, the conditions of existence will not yield to man's perversity, nor relax because of his ignorance or weakness. "Obey or suffer," is the alternative.

Ore Crushing.—No. 3.

[Written for the Press by J. RICHARDS.]

Anyone acquainted with the processes of casting and annealing such pieces is aware of the uncertainty in deep sections, and that a central core is the surest way of avoiding inherent strains.

Stamp stems can be of cast iron, formed solid with the heads and tappets so as to be cheaper than the present form. In the Kendall movement and some others the vertical adjustment to compensate for the wear of dies is attained by shifting the cams so that fixed tappets are no objection.

These remarks upon the mechanical conditions to be met in constructing hollow stamps might be extended indefinitely, but enough has been said for the present purpose. The chipping of dies, clogging, size of hearings and so on can all be as well provided for as in the case of solid dies.

In comparing air, applied as indicated, with water, as at present employed, and keeping in mind the requirements before noted, we have first freeing the stamps from finished particles. This function water performs in a very imperfect manner; there are no currents in one direction to permanently carry off the particles; only the "swash" of the stamps. As soon as they raise the water flows back, carrying with it first the lighter and finer particles, which should be removed from the battery, and lastly the larger particles. With air the fine particles would be drawn to the center as the stamps raise and he carried off permanently if fine enough. There would be no waiting for them to be dashed by chance against screens. The coarser and heavier ones that found their way into the air duct would fall back again at the center of the dies, leaving the coarser ones at the periphery.

The second requirement, separation of fine particles from the coarse ones in the battery, is a function still more imperfectly performed by water. Fine particles, being more readily conveyed by the water, are carried farthest and to the top, but the conditions of working permit their mixture over and over again with the unfinished pieces. Separation by suspension cannot be said to take place, because such separation can only be performed by regular currents of nearly uniform strength. In water stamping separation is more the result of accident, and performed mechanically by the screens. With air the whole operation is different, regular currents can be maintained and so regulated that the "selection" it may be called would be complete. In the separation of other material, grain for example, ascent or descent of the particles is governed by the least difference in their gravity or friction, if of irregular form.

Air currents have been employed with some success in separating or precipitating gold from pulverized quartz or placer sand. Such a process shows a power of selection far beyond what would be required in removing the finished particles from a battery.

The third requirement named was the removal of pulp, or sand, from batteries. In respect to water as an agent for such removal, some of the previous remarks will apply. The wash through screens is in a sense accidental, not a direct result from a sufficient cause, but a forced result, with water as an assisting medium. To illustrate the difference between air and water as a means of removing the finished pulp, or sand, let it be supposed that a battery is fed with sand fine enough to pass through the screens. If water is used the delivery will not be much faster than if stone is fed from the breakers, but with an air current through the dies the probability is that the sand would all be drawn out as fast as it came between or near to the dies, and the battery he cleaned as rapidly as the current could carry the material.

The inference is, that this function, which water performs most imperfectly of all, would be that one most thoroughly accomplished by air.

Suspension and precipitation, named as the fourth condition, have already been explained as depending upon maintained currents. In water, when there are no direct currents, precipitation, or suspension, is the result of agitation or indirect currents. The limited quantity of water that can be used prevents the use

of direct currents. With air there is no such limit. Precipitation would be much the same whether air or water were employed. The mobility of particles would no doubt be greater in the case of water, unless the material was thoroughly dry in the air process, so there would be no adhesion from moisture.

In the application of air to dry crushing screens could be dispensed with. On the importance of this point no remarks are required.

The protection of machinery from dust would also be a gain resulting from the use of induced air currents.

The abrasives wear of iron casings or other parts from sand passing through, is easily avoided. A double air lock could be employed, or what would be no doubt the most simple plan, stamps could be connected by pipes with a large receiver into which the induction pipes would lead. This receiver could be made large enough to act as a temporary receptacle for sand or pulp, also to slow down the air current to any desired degree, so as to permit precipitation. By exhausting this receiver no dust or sand except that so fine as to be held in permanent suspension, would pass through the fans.

The writer, in 1861 and 1862, resided in Ohio what is believed to be the first pneumatic conveyors for dust and shavings used in this country; he subsequently introduced the system in Europe, and has from the first been intimately acquainted with the application of air currents in the sand-hast processes both in this country and in Europe.

This latter process in its various forms has no doubt led to the most thorough experiments in abrading hard material that have ever been made. These facts are mentioned to show that the conclusions in respect to ore pulverizing processes are not wholly from inference, nor without experience in analogous branches of engineering practice. The conclusions reached are as follows:

1. The failure of water to perform in a perfect manner the required functions in wet crushing renders that operation much slower than it would otherwise be.

2. That mineral stone of all kinds is more friable, and can be pulverized at less expense when dry.

3. That air currents applied as before described, will perform the functions required in dry crushing much more effectually than water does in wet crushing.

San Francisco, June 20, 1880.

POPULATION OF SAN FRANCISCO.—According to the returns of Supervisor Langley, the population of this city is 233,066, including 20,549 Chinese. There will probably be a slight increase in the total by the addition of absent residents and through the correction of errors in the returns of some of the enumerators. The census makes our population some 70,000 less than the estimates of the city directory. Those estimates were extravagant, of course; but there is little doubt that many thousands of people have left the city within the past three years for Oregon and Washington Territory, and for the mining regions generally. During the five years preceding 1876 the population of the city was swelled enormously by the attractions of the mining share market, and when that collapsed the tide of population began to ebb and carried off more than the flood brought in. It goes without saying that the number of Chinese in the city has always been greatly exaggerated; but the cold facts show that we have many more than enough.

MINERAL WEALTH OF JAPAN.—The Japanese government has now a thoroughly organized geological survey, comprising a full staff of native surveyors, under an American chief, Mr. B. L. Lyman. In his first report of the progress of survey, Mr. Lyman describes a journey which he made with some of his staff from June, 1878, to February, 1879, extending over a distance of 2,800 miles. He reckons that the coal fields of western Japan contain about 620,000,000 tons, and if one-third be deducted for the working, there will remain 400,000,000 tons, representing a value at the cost of \$1,000,000,000. Inconsiderable as this is in comparison with the large and rich coal fields of other lands, it is quite equal in value to all the metal products except iron. The copper of all the workable mines scarcely reaches the value of \$750,000,000. The eight or ten gold and silver mines, which were formerly worked, and may be soon again, may, including the lead, antimony and tin mines, the workability of which is doubtful, be valued at no more than \$250,000,000. On the other hand, the value of the iron amounts to at least \$250,000,000,000 or 250 times more than that of the coal. The relative importance of the mineral products of Japan (excluding Yesso and the small coal fields of Kii, Ise and Iwakai) may be represented by the following numbers: Iron, 1,000, coal, 4; copper, 3; and all other metals (chiefly gold and silver), 1. The total value of these products reaches the sum of about \$252,000,000,000—i. e., just as much as the coal fields in Yesso, which in other respects is so poor in natural products. Mr. Lyman gives some details concerning 24 of the hot springs in Shimotsuke, Uzen, Iwashiro and Ugo, and a table of the petroleum springs of Japan, according to which by far the most numerous and productive are in Echigo and in Akita, and the total delivery in the year 1879 was 4,525 gallons per day.

Ruins at Aztec Springs, in Southwestern Colorado.

One of the most interesting of the many groups of Aztec ruins scattered throughout Colorado, New Mexico and Arizona, are those at "Aztec Springs," located in a depression between the Mesa Verde and the Late mountains. It is said that, until within six or seven years, there has been a living spring at this place, located at the point marked on our illustration, the presence of which undoubtedly determined this as a desirable point for settlement. Hayden, in his report, says that these ruins form the most imposing pile of masonry yet found in Colorado. The whole group covers an area of about 450,000 square ft., and has an average depth of from three to four ft. This would give in the vicinity of 1,500,000 solid ft. of stono work. The stone used is chiefly of the fossiliferous limestone that outcrops along the base of the Mesa Verde a mile or more away, and its transportation to this place has doubtless been a great work for a people so totally without facilities.

The upper, probably principal, house is rectangular, measures 80 by 100 ft., and is built with the cardinal points to within 5°. The pile is from 12 to 15 ft. in height, and its massiveness suggests an original height at least twice as great. The plan is somewhat difficult to make out on account of the very great quantity of debris.

The walls seem to have been double, with a space of seven ft. between. A number of cross-walls at regular intervals indicate that this space has been divided into apartments, as seen in the plan.

The walls are 26 inches thick, and are built of roughly-dressed stones, which were probably laid in mortar, as in other cases.

The enclosed space, which is somewhat depressed, has two lines of debris, probably the remains of partition walls, separating it into the three apartments, *a*, *b*, *c*. Enclosing this great house is a net-work of fallen walls, so completely reduced that none of the stones seem to remain in place; and I am at a loss to determine whether they mark the site of a cluster of irregular apartments, having low, loosely-built walls, or whether they are the remains of some imposing adobe structure built after the manner of the ruined pueblos of the Rio Chaco.

Two well-defined circular enclosures, or *estufas*, are situated in the midst of the southern wing of the ruin. The upper one, *A*, is on the opposite side of the spring from the great house, is 60 ft. in diameter, and is surrounded by a low stone wall. West of the house is a small open court, which seems to have had a gateway opening out to the west, through the surrounding walls.

The lower house is 200 ft. in length by 180 in width, and its walls vary 15° from the cardinal points. The northern wall, *a*, is double, and contains a row of eight apartments about 7 ft. in width by 24 in length. The walls of the other sides are low, and seem to have served simply to enclose the great court, near the center of which is a large walled depression (*estufa B*). No other ruins were observed in the neighborhood of these, although small groups are said to exist along the base of the Late mountains, a few miles to the southwest.

The little squares which surround the more imposing portions of the ruins are probably the remains of less pretentious dwellings. They are not of uniform size; neither are they arranged in regular order. The walls are simply marked by low lines of loose rubble, the quantity of which would indicate nothing but a very low wall, and all of which, as well as the larger structures, when occupied, were covered with some kind of a roof. As they now appear, they are more like a cluster of open pens, such as are used at the present time by the Moqui tribe of Indians for the keeping of sheep and goats. A somewhat singular circumstance may be noticed, in connection with this portion of the ruins, viz.: the fact that the number of minor divisions in dwellings upon each side of the open or dividing space is exactly equal in number—70.

CAM AND TAPPET.—A correspondent asks whether it will require more power to lift a 750-pound stamp, 95 times a minute to a given height, with the center of the tappet 10 inches from the center of the cam shaft, than it would to do the same work in the same time, with the center of the tappet directly over the center of the cam shaft. Our answer is that the same power will do the same work in the same time in either case, provided the friction in both cases is the same. It is simply the old question of a long or short lever in a new shape—what you gain in power you lose in speed.

PERSONAL.—Bierstadt, the artist, and Capt. James B. Eads, the civil engineer, are announced to arrive here this week. Capt. Eads, having been appointed Consulting Engineer of the State, will confer with the State Engineer in reference to the projected improvement of the Sacramento river.

The Plumas Eureka Mining Co. is contemplating adding 20 more stamps to its lower mill. This will give it 100 stamps in all.

Void Entries of Public Lands.

Commissioner Williamson, of the General Land Office, issued July 9th a series of detailed instructions to all registers and receivers which prescribe the regulations necessary for carrying into effect the law enacted at the last session of Congress for refunding all excess of payments of ordinary purchase money, fees and commissions of void entries of public lands. The act affects thousands of settlers throughout the Western States and Territories. The first section authorizes the repayment to "innocent parties" of fees and commissions paid by them on entries of fraudulent "soldiers' and sailors' additional homestead scrip," of which very large quantities were set apart in Western States some years ago. Commissioner Williamson's instructions require thorough proof of the innocence of applicants for relief under this section. The second section provides for the repayment of the purchase money and of fees,

tions for repayment are to be transmitted, together with all papers in the case, to the Commissioner of General Land Office, through the registers and receivers of the proper districts, who are required to make a due report upon each case transmitted, and the money finally found due will be paid out of the Treasury upon the warrant of the Secretary of the Interior.

MINING OPERATION IN IDAHO.—A company known as the Wood River G. and S. M. Co. was recently organized in Salt Lake City, says the *Tribune*, to work certain gold and silver mines in Alturas Co., Idaho. The officers are: Col. S. A. Merritt, President; J. D. Thompson, Vice-President; W. S. McCormick, Treasurer; Louis L. Davis, Secretary, and M. Lipman, Superintendent. The property is about 150 miles, over a good road, from Blackfoot station, on the Utah and Northern railroad. A few days since a discovery of wonderfully rich ore was made in the Bullion mine. Two assays were made, one of which yielded at the rate

commissions and excess payments in all cases where entries of public lands have been cancelled, or for conflict, or where from any cause the entry has been erroneously allowed by local land officers and cannot be confirmed, and also for refunding the extra \$1.25 per acre paid by settlers for lands supposed to be "double minimum lands," within railroad limits, but afterwards discovered to be outside of such limits, and therefore purchasable at the ordinary minimum price of \$1.25 per acre. All these repayments may be made to the party who made the original entry, or to his heirs, executors or administrators, or to any assignee specially authorized to receive such repayment, but the mere conveyance of land will not be deemed to carry with it the right of repayment, unless expressly so stated in the assignment. Where there has been a conveyance of land and the original purchaser applies for repayment, he must conclusively show he has indemnified his assignee, or perfected the title in him through another source. Assignees of title to land must show by affidavit otherwise that they have not been indemnified by their grantors for failure of such title. Where there is a specific assignment of purchase money, evidence of non-indemnification by grantor is not required. In case of desert land entries, assignees of purchase money are only assignees. Recognized applica-

per ton of 954 ounces in silver, with 68% of lead, and the other 500 ounces in silver, with 60% of lead. The Bullion is described as being over 80 ft. in width, between lime and quartzite, with 3 pay streaks running through it on the surface. One is 20 inches wide on a hanging wall, and seems composed of such ore as gives the large assay noted above. The next is near the center and is about 3 ft. in width, while the third is on the foot wall and is 20 inches wide. The two latter strata carry the 500-oz. ores. The Bullion discovery was made only a few days since, and the result has been to advance the stock \$10 per share. The company will set 17 men to work this week and commence at once to ship ore to this city. The strike in the Bullion is considered one of the most important ever made in the Northern country.

The plan for utilizing Genesee falls is really being carried out. The power is to be controlled by letting the water fall into perpendicular cylinders in such a manner as to compress air with tremendous force; and this air is to be conducted in pipes to various points for use in running machinery. The first novel application of the power will be to the propulsion of street cars. If the scheme proves successful, Niagara will be tried.

Letter from the Comstock.—No. 3.

EDITORS PRESS.—The declaring of a dividend by the Con. Virginia is considered by a good many as the foreshadowing of a better era, but why is more than anyone can tell. The old Bonanza mines might declare a good many dividends yet if the proceeds of the tailings, which are now being worked "very close" by the owners, were to go to the stockholders. Had the same care been taken to work the ore close, these dividends would have gone right on to date. The same steady preparation still goes on at the north end. I am pleased to say that there are hopeful signs in the south drift on the 2500 of the Union, and it is about 15 ft. in quartz that runs from \$2 to \$25. The other drifts mentioned in my last letter have been extended at about the usual pace, without encountering anything worthy of note.

On Friday there was talk of the northeast drift from the Union shaft being in rich ore, but this is most improbable. No one expected it at that point, and unless the ledge has been cramped up, like a boy with the stomach-ache, there is nothing in such a report. The north drift of the 2400 of the Sierra Nevada has now been extended nearly 1,000 ft., almost long enough to run some cross-cuts from. A chamber is being cut out in the west drift of the 2300 at a point 253 ft. from the beginning. The above is simply the state of the mines at that point, and it seems rather common-place to people who are daily looking for some big improvement. If the persons who are so impatient over the slowness of the work, would but spend a couple of days in the lower levels and see for themselves how much has been done, and how much yet remains, they would be quite content to wait a while yet.

Bodie stocks really deserve more attention than they are now receiving. The camp is not so easy of access as Virginia City, and comparatively few people reach it. During the past few months some of the leading capitalists of the coast have given the Bodie mines a thorough inspection, and only speak of them in the highest terms. The Noondays are now looked upon with much favor. The mines are at present paying off a heavy indebtedness, and when they get this dead horse out of the way, no one need be surprised at the suddenness and extent of their prominence. Woe to the man who at that time does not have a few of the shares laid away. Experts agree that there is enough ore now in sight to keep the mills running for years. When the company gets out of debt for its splendid machinery it will positively pay dividends. The Standard is also in prime condition, and in the fall, numbers more, now considered small fry stock, will come into prominence. The new road now being opened from Carson will materially advance the interests of the Bodie district, and will also open up a country 150 miles further south. A good deal is being said in the Carson papers about the Zabriskie mine. Numerous attempts have been made to sell it, but they have failed to find a customer. So far about the only ore that has been found exists in the imagination of the writers who hold the stock.

The talk of putting men to work above the tunnel level for \$3 has as yet taken no shape, and the miners who say that no work shall ever be done at that price are now engaged on the narrow-gauge road to Bodie at \$1.50 a day. While this stubbornness is being kept up, the miners are being discharged from the Comstock in scores every day, and the vitality of the ledge is ebbing away. Were there a reduction in milling and railroading charges the Miners' Union will, it is said, agree to come down; but each side waits for the other. So far as the railroad company is concerned, D. O. Mills will make no reduction, even if the Comstock sinks through to China. He has always maintained this policy, and always will. There is a general feeling this year that a Legislature must be elected which will regulate this state of affairs, but experience teaches us that we must not hope.

In a week from now the Union pump will be running. It will take water from the 2500 level and enable work to go on east of the ore body. It is the most important piece of work done on the ground for nearly a year. The Yellow Jacket stockholders are still paying enormous sums of money to keep the pumps running, when by connecting with the south branch of the Sutor tunnel the water might all be carried out that way. Why this is not done is more than anybody knows.

The report that John Mackay was about to leave the Comstock during the present month has been used by the bears. He will not go to Paris before fall, when Col. James Fair will return and take his place. Mackay will then not be gone over two months.

HAND DRILL.

It is probable that a hydraulic balance pump will presently be put in at the Chollar-Norcross-Savage shaft. No such pump is now in use anywhere in the United States. Such pumps are used in some of the deep mines of Germany.

MINARET district is the last one organized in Mono county. This district immediately joins Lake on the north, and North Fork and Mountain View on the south. Fresno county men own many of the claims.

Our Abnormal Gold Coinage.

From the 30th of June, 1849, to the 30th of June, 1879, our mints have been steadily operated to the end of making it impossible for our people to use gold in their daily business dealings, as the French and English people do, by coining it into 20-dollar pieces, as may be seen from the fact that out of a gold coinage for these 30 years of \$999,480,339, no less than \$898,239,120 were in these same 20-dollar pieces, a coin altogether exceptional among commercial nations. Any system more cleverly contrived to force our people to carry on their daily dealings with each other in paper or credit money, it would be impossible to conceive, or one which more thoroughly sets aside gold for the exclusive convenience and behoof of the capital classes and moneyed institutions of the country, while facilitating its exportation abroad, there to be turned into sovereigns for the English, and into four-dollar pieces for the French people.

Strange to say, never a word had been said in opposition to this utterly exceptional species of money or in exposure of the evil effects of it, until this journal pointed out its features. However, since the present director of the mints has been in office there has been a disposition apparent to give the people some use of gold; at least, so far as to coin five-dollar pieces which, let us note, are 20% larger than the largest coin of the immense gold circulation in France, and a considerable fraction larger than the largest coin minted in England and Germany. But even with the best intentions, Mr. Burchard, as yet, has been unable to lift the mints out of the deep rut in which they have been running these 30 years.

For May, we perceive, that while an aggregate gold coinage of all the mints of \$4,427,845, only \$980,000—about 22%—were of these 20-dollar pieces, as much as \$1,912,300, or 40%, however, were in 10-dollar pieces, which are as exceptional, and nearly as objectionable for currency uses as the double eagle. Therefore, 62% of the May gold coinage was of these uncurrent pieces, and a continuation of the system which reverses the practice of all other commercial peoples, whose habit it is to use paper in large transactions and keep the precious metals largely for currency in retail dealings. The balance, 38%, was in five-dollar pieces. As in the last 12 months, the coinage of double eagles has not amounted to less than \$30,000,000, surely our mints might now be rightly turned aside for some time from their coinage, without inconvenience to anyone, and coin, say one-fourth in eagles, one-half in half eagles and one-fourth in quarter eagles. There is enough double eagles in the Treasury to pay out to depositors of bullion, who may exact such coins in return. The coinage exclusively of small gold—half and quarter eagles—would be timely and wholesome as a check upon exportation, made so facile and convenient, under the double eagle system.—*Mining Record.*

Reporting by Telephone.

The method of reporting late debates in the House of Commons by telephone, lately adopted by the London *Times*, is thus described by that journal. A type-setting machine has for some time been used in the office, by which a fair workman can attain an average speed of 100 lines an hour, even when composing from manuscript which he has to read for himself; and this speed can be doubled, or nearly so, when the operator is assisted by a reader, and thus composes from dictation. Now the telephone has been brought into use in connection with this machine in the following mode. Having obtained the permission to lay down the necessary wires we formed a new connection between the House of Commons and the office, and placed one of Edison's loud speaking telephones at either end. The immediate result of this arrangement has been to bring the compositor at the machine into direct communication with the parliamentary reporter at the House and to enable the debates to be reported and printed from half to three-quarters of an hour later than had previously been possible. The notes made by the reporter can be read directly into the telephone-receiver in a room adjoining the gallery either by the reporter himself when relieved or by another person employed for the purpose, and the compositor at the machine, in the office, sits with his ears in juxtaposition with the other terminal of the instrument.

The plan which has been found the most efficacious for the purpose of shutting out distracting sounds of other kinds is to place the disc of the telephone above and behind the compositor and then to arrange two tubes, each with two trumpet-shaped extremities in such a manner that these extremities are applied at one end to the two sides of the telephone disc and at the other end to the two ears of the compositor. The compositor is also furnished with a speaking instrument, with a key for ringing a bell and with a bell which is rung from the House—a simple code of bell signals, consisting of one, two, or three strokes, sufficing for the ordinary requirements of each message. The compositor announces by the bell that he is ready, receives a sentence, strikes the bell to indicate that he understands it, sets up the type with his machine, strikes the bell again for the reader to continue his dictations, and so on until the work is carried as far as time will allow. If there is any doubt or difficulty about the words a bell signal will cause them to be repeated, or explanations can be sought

and received by direct vocal communication. In this power indeed resides one of the chief advantages of the method, and one which ought to lead to greater accuracy than has ever previously been attainable. The names of people, places, etc., can be spelled out letter by letter if there is any doubt about them.

The Mongollon Mines.

A correspondent of the Los Angeles *Herald* has furnished that paper with the following account of the Mongollon mines, New Mexico:

On looking over some of the Pacific coast papers I see with great pleasure that the attention of California miners and capitalists has been turned in the direction of the late unexcelled discoveries of silver ore in Arizona and New Mexico. Nevada may have shown larger ore bodies, but as far as rich ores are concerned the present finds in Arizona and New Mexico will be considered remarkable, especially as the new discoveries are not confined to one or two localities, but cover nearly every known mountain range in the two Territories. So much has been written about the developments in the central and southeastern part of Arizona that it will not be necessary for me to touch upon their different merits, and I will confine myself to giving a short description of our new mining camp in the Mongollon mountains.

The mines are situated a distance of 80 miles northwest from Silver City, and near the San Francisco river, in the first rise of the Mongollon mountains, and are easy of access. The locality is very well supplied with timber of every description, and as far as water is concerned the supply is unlimited, six running streams crossing the belt at right angles, whilst numerous springs on the mountain sides furnish the necessary drinking water for the higher lying mines. The formation of the camp is granite and porphyry, the veins running north and south, and cropping in bold relief, traceable for miles, showing high-grade pay chimneys on almost every location that has been made. All ores found in the district are of the copper and silver glance variety, and assay from 15% to 85% copper, and from 30 ounces up to 1,700 ounces of silver, the great average of the ore running about 35% copper and 250 ounces of silver. The veins are in granite, and are generally true fissure, with a marked dip to the northeast, and show a width of from 2 to 40 ft.

The Silver Bar mine, the best developed mine in the camp, crops for a distance of 800 ft. in solid metal. A crosscut being driven in the vein has penetrated a body of ore 17 ft. wide and rich in silver glance and native silver, exposing a bed of ore that can only be guessed at by the thousands of tons, of exceptional richness. A great many other locations show similar results on a somewhat smaller scale.

The Mongollon mines were discovered several years ago, but, on account of their remoteness from the nearest point for supplies, and the continued harassments from the hostile Indians, the developments have not gone ahead on as large a scale as would have been the case if the mines had been found in almost any other locality. As soon as the Indian question is settled, the Mongollons will show what they are—they will show the highest and richest mining camp south of Colorado.

DEMAND FOR GAS ENGINES.—Those connected with the manufacture of illuminating gas in this country appear to be gradually coming to a sense of the necessity of building up additional markets for their product. They are now making strong efforts to aid the introduction of gas engines. At a recent meeting of the Western Gas Association, at Indianapolis, Mr. J. O. King, president, in his address stated that the demand for gas engines is so great that manufacturers are unable to meet it with any promptness. Mr. Ramsdell, of Vincennes, Ind., speaking on the subject, gave a brief account of the experience which he had had with the Otto silent gas engine. A 17-horse power engine operated two elevator belts, lifting the grain in 8 and 12-inch buckets 60 ft. high, 10-inch conveyers 135 ft. in length, one wheat cleaner and fan and one pump. To do this it consumed 200 cubic ft. of gas per hour. The chief advantage brought out was that it is admirably adapted for light and intermittent work. In addition to this wheat machinery there was complete machinery for handling corn, besides the elevator and conveyers, used also for the wheat, one No. 2 corn sheller and machinery, etc. Another, a 14-horse power engine, operated the machinery of a local newspaper, from three to four hours a day, at a consumption of 1,000 cubic ft. of gas per month. The gas engineers, it seems, are considerably impressed with the importance of the subject.

THE TAY BRIDGE DISASTER.—The Tay bridge commissioners have presented two reports. The majority report censures more or less severely the contractors, engineer and North British Railway Company. The design of the bridge is condemned, and the company charged with neglecting to keep it in proper repair. Although the construction of the bridge was faulty, the commissioners believe it might have weathered the storm and lasted for years had it been kept in thorough repair. The minority report arrives at substantially the same conclusion, but differs on matters of detail.

ACCORDING to a German journal, vessels of platinum are to some extent attacked and corroded by the carbonates of potash and soda at their melting point.

Send for free circulars of information. Office of the **MINING AND SCIENTIFIC PRESS AND PACIFIC RURAL PRESS**, No. 202 Sansome St., San Francisco.

INCERSOLL ECLIPSE ROCK DRILLS.

The Best and Cheapest DRILL in the Market.

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily belt over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-ltimbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,
49 Fremont St., S. F.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same, appliances for testing, roasting, etc. Under the heading of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the heading of "Leaching Processes" he gives the titles, Smelting, Mexican process, Chilean process, Knecht's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

ARITHMETIC MADE EASY BY ROPP'S EASY CALCULATOR.

This valuable work is used by thousands of farmers, mechanics and business men, and is highly recommended for its practical utility and convenience.

It embodies an entirely new system of calculation, by which a vast amount of figures and mental labor—required by the ordinary methods—and fractions with their complexities, are absolutely avoided.

It is so simple and easily comprehended that even the most illiterate is enabled, in a few minutes, to reckon with absolute accuracy and speed; while its original and rapid methods, benefit and delight the most scholarly.

It shows at a glance the accurate value of wheat, corn, rye, oats, barley, cattle, hogs, hay, coal, lumber and merchandise, from one pound to a car load, and for any price the market is likely to reach.

It gives the interest, simple and compound, on any sum, or any time, at six, seven, eight, and ten per cent.; the exact measurement of boards, scantlings, timbers, saw logs, cisterns, tanks, wells, granaries, bins, wagon beds, corn cribs, etc., the wages at various rates, for hours, days, weeks and months; besides numerous other important methods, rules and tables.

It is printed on fine tinted paper, is well and elegantly bound in pocket-book shape, and accompanied by a slate, slate, pocket for papers, and memorandum, which can be replenished in the two latter styles.

It answers the purpose of a pocket book and diary, and costs no more, although it was gotten up at great expense and labor, and is unquestionably one of the most useful publications ever issued from the press.

Price, bound in Fine English Cloth, \$1.00.
Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter or receipt by express. Address

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. 1880. A valuable and carefully written work. Postpaid, \$3.00. Sold by Dewey & Co., S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MIXING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

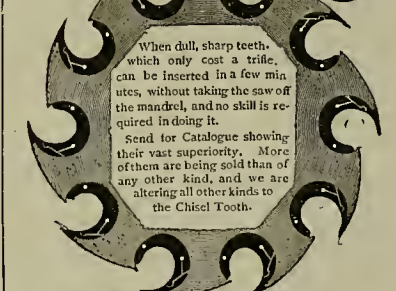

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 156 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$3.00 coin, postage free.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING JULY 6, 1880.

229,586.—EXTRACTING METALS FROM ORES.—T. C. Clark, Oakland, Cal.
229,590.—FIRE KINDLER.—H. Finck, S. F.
229,593.—FILLING GUNS.—L. Cutting, S. F.
229,606.—SAFETY CLUTCH.—B. E. Henriksen, S. F.
229,599.—CHURN.—Geo. W. Freeman, Rocky Point, Cal.
229,619.—COMPASSES.—J. D. Little, Petaluma, Cal.
229,624.—DERRICK.—E. J. Marsters, Stockton, Cal.
229,636.—GUIDE ROLLER.—T. Pusey, Stockton, Cal.
229,625.—BILLIARD TABLE.—S. R. Mathewson, S. F.
229,632.—GRAIN SCREEN.—B. F. Pettit, San Luis Obispo, Cal.
229,637.—FAUCET.—C. C. Redmond and A. W. White, San Jose, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions* rendered upon patent cases in litigation, for the benefit of our readers:

DECISIONS OF THE U. S. COURTS.

Eagleton Manfg Co. vs. West, Bradley & Cary Manfg Co. et al.

U. S. Circuit Court, Southern District of New York.—Decided June 9, 1880; Wheeler J.

1. If a patent was not accompanied by an application the date of the patent would be deemed the date of the invention; and the application to be effective evidence to carry the date of the invention back to its own date, must be an application for substantially the same invention for which the patent is granted, without material variation or addition.

2. When the application fails to take the date of the invention back of the date of the patent, and the defendant makes out prior knowledge and use by others beyond any fair or reasonable doubt, as the law requires, the burden is shifted on to the plaintiff to show invention or discovery by the patentee still prior to that.

3. An inventor need not know all uses to which his invention is capable of being put, but there must be some patentable invention patented before any use of it can be covered by the patent.

4. The proceedings of the Patent Office are presumed to be regular and founded upon proper proceedings; but they must necessarily be founded upon the application of living persons or their personal representatives, such as the law recognizes, and not upon those of persons who are merely supposed to exist, and should be founded upon the oath of the inventor or his personal representative in accordance with the statute.

5. An application made and sworn to June 26, 1868, by an inventor who died in February, 1870. Amended November 7, 1871, by the introduction of the substantial part of the thing patented by persons who had been his attorneys, unsupported by the oath of his personal representative, not a valid foundation for a patent.

6. Patent No. 122,001, dated December 19, 1871, issued to J. Joseph Eagleton, Sarah N. Eagleton, Administratrix, for an improvement in Japanese furniture springs, granted upon such an application, never had a valid existence.

Bill of complaint dismissed with costs.

Sinclair et al. vs. Backus.

U. S. Circuit Court, District of Massachusetts.—Decided January 27, 1880; Lowell J.

1. Quere whether, when a patentee has made an original invention which is confessedly an improvement upon all old machines, he is conclusively presumed to have known every lost and forgotten machine in the line of his art, and therefore must prove invention over the best of them, as he undoubtedly must be presumed to know of any machine which fully embodied his invention.

2. A patentee is entitled to protection for improvements made by him, notwithstanding the prior existence of a device having the same capacity, but differing in structure.

3. Experimental use occurring more than two years prior to the filing of the application is not fatal to a patent, even though the use was for the purpose of satisfying others as to its utility.

Decree for complainants.

* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

EXTRACTING METALS FROM ORE.—Thomas C. Clark, Oakland, Cal. Patented July 6, 1880, No. 229,586. The object of this invention is to perform the disintegration and desulphurization of ores so as to bring the said ore into proper condition for easy pulverization, and the precious metals contained therein into a suitable form for amalgamation, by freeing them from the union and influence of haser metals. In order to accomplish this object, the ore is crushed into pieces about the size of ordinary Indian corn. That portion containing sulphurets generally becomes finer, since it is more friable. The object of crushing it to this size is to prevent loss of gold and facilitate washing operation. The ore, after being crushed as described, is placed in an ordinary roasting furnace. After being roasted for a suitable length of time, the heat is raised, so the sulphur will turn freely, after which the heat is let down again, a free supply of oxygen being furnished during the whole process of roasting. After the ore has become dead and lies like sand in the furnace, and no more ecintillation is apparent, it is heated up to a good red heat, but not made too hot. In a suitable receptacle beside the furnace a cold bath is formed, in which the ore is drawn while in its heated condition, fresh from the furnace. This bath is formed of a solution of salt, prussiate of potash, and caustic soda or caustic potash.

DIVIDING-COMPASS.—John D. Little, Petaluma, Cal. Patented July 6, 1880. No. 229,619. In this ordinary carpenter's compass an arc is attached to one leg and passes through a slot in the leg, a set-crew passing into this slot, so as to impinge on the side of the arc and secure the moving leg to the arc. After a measurement has been taken, this set-crew is turned and the measure retained. In doing this, both hands must be used—one to open or adjust the compass, and the other to set the screw. This set-crew, moreover, wears out rapidly and does not always work satisfactorily. In this improved method of securing the moving leg to the arc, only one hand has to be used to manipulate both compass and retaining device—this retaining device being of such a character as to be very durable and easily operated.

CHURN.—George W. Freeman, Rocky Point, Sierra county, Cal. Patented July 6, 1880. No. 229,599. The inside of the churn has peculiarly shaped corrugations, formed longitudinally through it, so as to prevent the butter from slipping while working it. Small strips of wood extend from the ends of the churn lengthwise and fit into the backs of the corrugations, so the zinc which forms a cooling cylinder will not be bent, and the form of the ledges or corrugations will not be altered. This enables the churn to be cleansed much better than could be done if strips of separate material were introduced to form the ledges. The device also contains other novel features which form a complete butter-worker without the necessity of using hands or other apparatus.

GRAIN SCREEN.—Benjamin E. Pettit, San Luis Obispo, Cal. Patented July 6, 1880. No. 229,632. This invention relates to certain improvements in screens or sieves for separating grains, and cleaning grain of chaff, and other worthless seeds and foreign substances. It consists in the construction of the metallic plate of which the sieve is made, with slits which are cut and raised to such a height and width; and to permit the passages of seeds, grains and other matter it is intended to save, those of larger size not passing through, but being directed off at the end. The peculiar construction of the sieve is such that this separation depends on differences of size or shape, and not on specific gravity of the grain or seeds, and different sized slots may be used for different grain.

BILLIARD TABLES.—S. R. Mathewson, 28 New Montgomery St., S. F. Patented July 6, 1880. No. 229,625. This invention consists in forming the cushion or sides of the table of one or more pieces of straight wire passing around studs at the corners, in combination with an adjusting device so arranged that the slack may be taken up in order that the wire may be kept at such a tension as to provide an elastic medium for the balls to rebound from. It also relates to a peculiar method of forming the studs which control the wire. It also further consists of peculiar construction of the surface in combination with a billiard table.

SAFETY CLUTCH.—B. E. Henriksen, Throlock, S. F. Patented July 6, 1880. No. 229,606. This invention relates to certain improvements in elevators and hoists of any description, and its object is to secure the same against the sudden fall or violent and rapid descent usually caused by the breaking of the cable or derangement of the hoisting apparatus. It consists in the employment of certain levers and catches in connection with the elevator frame, which will be actuated by any unusual speed of the descending cage or platform, and cause it to stop.

AIR COMPRESSOR.—Henry Richmann, S. F. Patented June 29, 1880. No. 229,468. This invention consists, first, in providing a peculiarly shaped double crank for communicating the power from the steam cylinder to the air compressing piston, the crank for the cross-slide of the steam cylinder being formed in one piece, with that for the cross-slide of the air cylinder. Second, in providing for the pistons of the air cylinders double piston rods, whereby the pistons are more evenly balanced and room left in the cylinder heads for valves of large area. Third, in constructing the pillars and bed pieces of the frame work hollow, and so connecting them that said frame shall act as an air receiver.

FIRE-KINDLERS.—Henry Finck, S. F. Patented July 6, 1880. No. 229,596. This invention relates to that class of fire-kindlers wherein a series of hits of wood are coated with resinous, oleaginous matter, and consists in fagoting or binding together the hits of wood or other material by means of the tenacity of the inflammable matter into which they are dipped, so as to avoid the use of nails, or tacks, or offsets in fastening them.

GOLD-SAVING APPARATUS.—Bryan Tyson, Washington, D. C. Patented July 6, 1880. No. 229,650. This invention relates to certain improvements in apparatus for saving precious metals, quicksilver, etc., which may be contained in pulp, tailings or other form of pulverized ore; and it consists in an adjustable trap located in the main flume to lead the tailings to a short sluice provided with transverse, fixed and movable riffle bars, the tailings then passing to an oscillating pan or jigger for concentration.

The State Fair of 1880.

The State fair of 1880, commencing September 20th and ending September 25th, will be the first under the auspices and direct control and management of the State. This fact should and will invest its proceedings with a more official character, and give them a greater dignity and weight. Its records will go abroad as State documents, stamped with official authority, and hearing the indorsement of every citizen of the commonwealth. It becomes, therefore, a matter of greater importance than heretofore, not only to the State, but to each individual citizen interested in the welfare of the State, that the fair should be made a true and full exposition of all the known material resources of the territory within our borders, of all the industries and industrial productions of the State, and of all the tangible evidences of the substantial prosperity of the people.

While the members of the Board of Agriculture, who give their time and services without fee or reward, except that which comes from the satisfaction of having benefited their adopted State, propose to exert their best endeavors to make the society and the fair what they should be, they know that they can do but little unless their efforts are seconded by the people who develop those resources, conduct and manage those industries, and enjoy that prosperity. What is true of the State Board of Agriculture in this respect is equally true of each District Board. They can do but little towards advancing the material prosperity of their districts without the aid of the people of the districts. With this aid, the District and State Associations, as now organized, working in harmony for a general purpose, may contribute greatly to this general prosperity, and add millions annually to the wealth of this State.

The first thing for any one to do who desires to show the products of his farm or workshop is to send to I. N. Hoeg, Secretary, Sacramento, for a copy of the new premium list. It has been issued by the State printing office in excellent style, and contains a full enumeration of awards, rules for competition, etc. There are over \$20,000 offered as premiums, and the money, so far as our examination goes, seems better apportioned than it has ever been before. There is also provision for fair awards to worthy articles which may not be named in the list, so that anything good and valuable should be brought forward.

There will be especial encouragement to exhibitors, from the fact that the Central Pacific Railroad Company will carry all articles and animals exhibited at the fair, over its respective routes, free of charge, under the following rules: Charges will be collected for transportation to the fair. After exhibition, the articles, if consigned direct to original shipping point, and the ownership has not changed, will be returned free; and the charges paid for transportation to the fair will be refunded by the railroad agent at destination, upon presentation of the Secretary's certificate of exhibition and surrender of the expense bill for freight charges paid at Sacramento. The same company will issue excursion tickets to all parties going to the fair and returning, at about half price.

For the accommodation of families and parties desiring to camp out during the fair, the board have secured ample grounds for that purpose within easy access to the pavilion and the park. By availing themselves of this opportunity, the attendance at the State fair may be made a pleasant camping tour by parties at a distance, at small expense. Our climate is most favorable for the introduction of this custom while attending our State fairs.

The managers of this year's fair seem to be making extra efforts for the success of the exhibition, and we trust they will attain it. On another page of this issue we print the speed programme of this year's fair.

"DAILY JOURNAL OF COMMERCE."—An interesting event in the history of commercial journalism in this city is the appearance, during the present week, of the first issue of the *Daily Journal of Commerce*. The new *Journal* is from the well-known establishment which has published the weekly of the same name for a number of years. The great trade of this city calls for a daily record of market values, the movements of merchandise and produce by ship and rail, and other matters which enter into correct judgments on trade questions. Into this field the new *Daily Journal of Commerce* will enter, and it should receive the support and encouragement of the mercantile interest.

EFFECTS OF THE BICYCLE.—It is common now in the English metropolis to meet with young men who are prematurely round-shouldered and walk with bent knees and a sort of arch-like movement. Riders of the so-called "steel horse" may be interested to know that this ungraceful appearance has been named the "hicycle back" in honor of the pastime that causes it.

A LETTER from Hequicht, on the west coast of Vancouver's island, states that at that station alone 900 fur seals have been hought. The few Indians settled there have made over \$5,000 in two months. Some made as high as \$120 apiece in one day; many from \$30 to \$80 each.

News in Brief.

TOM TAYLOR, the dramatist, died suddenly in London, July 12th.

CONSIDERABLE damage was caused by a cloud-hurst near Yreka, Siskiyou Co., July 5th. HENRY M. STANLEY has been made a doctor of philosophy by the German Academy of Naturalists.

The entire press of Texas, without exception, condemn in the strongest terms the acquittal of Currie.

Two colored boys have passed the examinations for entrance to the Reading (Pa.) High School.

In this city Robert Neil, a twelve-year-old boy, committed suicide rather than he returned to school.

The increase of acreage in grain in Wasco county, Oregon, is five times what it was three years ago.

From the agricultural districts of France come reports of good weather and prospects of a rich harvest.

THERE were 40,000 cars huilt in the United States last year, and there will be about 50,000 huilt this year.

THE Snake river in Oregon was rechristened by the Villard party, and now goes by the name of the Lewis river.

ADJUTANT-GEN. JONES of Texas reports that the State has about 6,000 criminals at large, 1,000 of them murderers.

A BANQUET took place in Liverpool, July 5th, given by the United States Consul in honor of Independences Day.

A COOL wave struck Salt Lake July 12th, and snow fell in the Wasatch mountains to a depth of four inches.

THE peasants of Lombardy live chiefly on black bread and a broth made of rices, a few vegetables and rancid oil.

It is said that young laborers will soon become scarce in Ireland if the present rate of emigration continues.

ONE of the census enumerators of McLennan county, Texas, found a widow 35 years old with a son 27 years of age.

IN Mono Co., Cal., there is a giant juniper tree fully 60 ft. in circumference, with limbs five to six ft. in diameter.

SAYS the *Merced Express*: A good crop of wheat in this county is always succeeded by a large fall crop of weddings.

THE visible supply of petroleum is the largest known in the history of the trade, being estimated at 9,000,000 to 10,000,000 barrels.

SAMUEL P. BOWLES, ex-County Engineer, of Cincinnati, convicted of forging county bonds, was sentenced to ten years in the penitentiary.

THE *Big Horn* was the first boat out of the Yellowstone this season, and brought down 5,000 buffalo robes and large quantities of furs.

BERKELEY SPRINGS, Va., is said to be the oldest watering place in the country, dating from the aborigines, who discovered the virtues of the waters.

A SUIT for \$25,000 has been brought against the city of Augusta, Ga., for injuries to a child that had been gored by a cow running loose in the streets.

THE old whipping-post in Raleigh, N. C., which had been used as a hitching-post since 1868, has disappeared from its place near the Court-house.

LIGHT wines, bread, coffee, salad, vegetables and fruit form the staple diet of the working-men of Paris. The vegetables are good, plentiful and cheap.

THE Belgian Bishops have advised the Vatican that their action will be more free and powerful since the rupture of diplomatic relations with Belgium.

A BRITISH ship has sailed for Texas with 3,500 barrels of oil, made for the purpose of preserving railroad ties and bridge timbers under a new process.

THERE are 38 Masonic Lodges in Washington Territory, representing something over 1,000 members, St. Johns of Seattle being the largest, it having 80 members.

THE scheme of mutual aid among the Masone of Mississippi, inaugurated in February last, is an assured success. The membership within the year will number 2,000.

THE crops of able ladies who make *Demorest's Monthly* so attractive to their sex, has filled the July number with all manner of interesting and instructive things.

IN Switzerland, July 4th, there occurred a severe and widespread earthquake. A large area of wooded land was covered, and two persons are known to have been killed.

WHILE a mail agent of Little Rock was handling a mail pouch rather roughly, a loud explosion occurred inside of it. It was caused by a loaded revolver mailed by a Texan.

CALIFORNIA'S wool clip this year (spring and fall) will probably be not less than 35,000,000 lbs. The total value of it promises to be nearly double that of any preceding wool crop.

A DRUNKEN driver, July 12th, while driving from the Glen House to the summit of Mount Washington, N. H., capsize the stage containing nine persons, killing one and seriously injuring five others. He was fatally injured.

IN the heart of a large pine tree, recently cut down by Jonathan Oakley, of Unadilla Forks, N. Y., was found an Indian pipe of stone, with the date roughly carved on it, 1783.

A NEW YORK man was challenged to fight a duel the other day, and being at liberty to choose his own weapons, proposed a trip to Boston on a Sound steamer. The challenger backed out.

The Mechanics' Fair Daily.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the ELEVENTH VOLUME of the MECHANICS' FAIR DAILY during the FIFTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Tuesday, August 10th, 1880.

It will be of large size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resource and rapid progress of our great Western Community.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle by those who receive it freely at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive advertising and printing privileges, and will receive no advertising in the official catalogue and reports.

Our ten previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a more broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our coast.

DEWEY & CO., Publishers.

Office, MINING AND SCIENTIFIC PRESS, No. 202 Sansome street, N. E. corner Pine, San Francisco.

ST. MATTHEW'S HALL.—The next term of school at St. Matthew's Hall, San Mateo, begins on the 22d inst., next Thursday, as will be seen by advertisement in another column. The last term of this well-known institution was the most successful in its history, and the prospects now are that the next will be even more so. Applications for admission are being daily received. During the vacation the buildings have been thoroughly overhauled, renovated and put in an attractive condition; some addition to the school-rooms have been made and other extensive improvements carried out, as demanded by experience and the increased requirements for such accommodations. All its departments are perfectly arranged, and boys committed to its charge will be certain that their moral and physical welfare will be as carefully looked after as their mental training.

AMERICAN plows and other agricultural implements are being shipped from Tucson into Sonora.

DEAD RIVERS OF CALIFORNIA.—It is estimated that among the dead rivers of California lying up 7,000 or 8,000 ft. above the sea, there lies a treasure of more than \$300,000,000, the annual product being uniformly about \$8,000,000. In one little spot in Nevada county there has been taken out about \$100,000,000. Some of these dead rivers have a fall of 50 ft. to the mile, affording good opportunities for drainage, under currents, and all the various modern appliances for saving fine gold.

QUARTZ MILL BURNED.—The Leopard Co.'s mill, at Milltown, two and one-half miles from Cornucopia, was burned to the ground about midnight, July 12th. The mill was shut down and a watchman was guarding it. The fire started in the upper part of the building, and was evidently the work of an incendiary. The mill was insured by the company's creditors for \$15,000.

Healthful Waters.

TO THE RURAL PRESS:—In my late trip through Lake county, among the many resorts for health or recreation that it was my good fortune to visit, none impressed me more favorably than Anderson's Springs, both for the valuable and varied medicinal qualities of its numerous springs and the beauty of its surroundings, together with its cool and agreeable climate, even in the sultry days of June, making it a favorite refuge to the many toilers of our cities, tired and sick of body or weary of mind, aside from the health-giving properties of its water. All who have given them a trial pronounce them unsurpassed in this State. It is most emphatically a place of rest, of quiet, luxurious repose amid cooling shades and sparkling waterfalls, enlivened by the song of birds and the perfume of flowers. The hotel is kept by Mrs. Anderson and her accomplished daughters, who preside with equal grace in kitchen and parlor, and whose genial influence imparts a home-like feeling that is immediately felt by all visitors. Few stop here any considerable time without hoping to return at some future opportunity.

For dropsy, nervous debility and rheumatism, as well as for liver and kidney complaints, the water and hot baths are remarkably efficacious.

Anderson Springs are located just off the Lakeport road, about five miles from Middletown. The hotel carriage meets the stage daily for the accommodation of travelers. J. STRATTON.

July 13, 1880.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

In the Whole History of Medicine

No preparation has ever performed such marvelous cures, or maintained so wide a reputation, as AYRES' CHERRY PECTORAL, which is recognized as the world's remedy for all diseases of the throat and lungs. Its long continued series of wonderful cures in all climates has made it universally known as a safe and reliable agent to employ. Against ordinary colds, which are the forerunners of more serious disorders, it acts speedily and surely, always relieving suffering, and often saving life. The protection it affords, by its timely use in the throat and chest disorders of children, makes it an invaluable remedy to be kept always on hand in every house. No person can afford to be without it, and those who have once used it never will. From their knowledge of its composition and effects, physicians use the CHERRY PECTORAL extensively in their practice, and Clergymen recommend it. It is absolutely certain in its remedial effects, and will always cure where cures are possible.

FOR SALE BY ALL DEALERS.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

THE BEST NEWSPAPER FILEHOLDER AND ADJUSTABLE DRAWER can now be had at this office. It consists of elastic fastenings, with stiff, cloth covered side. Size suitable for a full volume of this paper, \$1. To our subscribers 75 cts., mailed postpaid.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

FRESH attractions are constantly added to **Woodward's Gardens**, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

J. G. COLMERLIL is requested to report to this office from Humboldt Co.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Chew Jackson's Best Sweet Navy Tobacco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Consolidated Virginia Mining Company,

Room 23, Nevada Block, No. 309 Montgomery St., S. F.

At a meeting of the Board of Trustees of the Consolidated Virginia Mining Company, held this seventh day of July, 1880, dividend (No. 52) of Fifty (50) Cents per share was declared payable on THURSDAY, the fifteenth day of July, 1880.

Transfer books closed until the 10th instant.

A. W. HAVENS,
Secretary.

DIVIDEND NOTICE.

OFFICE OF THE

Eureka Consolidated Mining Company,

Nevada Block, Room 37, S. F., July 15, 1880.

At a meeting of the Board of Directors of the above named Company held this day, Dividend (No. 50) of Fifty cents (50c.) per share was declared, payable on MONDAY, July 12, 1880, at the office in this city, or at the agency of The Nevada Bank of San Francisco in New York. WM. WILLIS, Secretary.

Office—Room 23, Nevada Block, No. 309 Montgomery St., San Francisco, Cal.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company,
San Francisco, July 2, 1880.

At a meeting of the Board of Directors of the above named Company, held this day, Dividend (No. 17) of Seventy-Five cents (75c.) per share was declared, payable on MONDAY, July 12, 1880, at the office in this city, or at the agency of The Nevada Bank of San Francisco in New York. WM. WILLIS, Secretary.

Office—Room 23, Nevada Block, No. 309 Montgomery St., San Francisco, Cal.

POWDER CONSUMERS.

Please take notice, that in the action of the VULCAN POWDER CO., against a firm known as R. W. Warren & Co., of this city, composed of Robert W. Warren and Robert H. Yates, they and their employees and agents were enjoined from making, vending or offering to sell or manufacture an "VULCAN" BLASTING POWDER. VULCAN POWDER CO.

DIVIDEND NOTICE.

The German Savings and Loan Society.

For the half year ending this date, the Board of Directors of THE GERMAN SAVINGS AND LOAN SOCIETY has declared a dividend on Term Deposits at the rate of six (6) per cent. per annum; and on Ordinary Deposits at the rate of five (5) per cent. per annum, free from Federal Taxes, and payable on and after the 15th day of July, 1880. By order.

San Francisco, June 30, 1880. GEO. LETTE, Secretary.

Some fine sunny offices (next to the PRESS office), to rent (at very reasonable rates), by Dewey & Co., at 202 Sansome street, corner of Pine.

PACIFIC MACHINERY DEPOT.

H. P. GREGORY & CO.,

Nos. 2 and 4 California Street, San Francisco.

Importers and Dealers in every description of

MACHINERY!

Sole Agents for the Pacific Coast for

BUCKEYE
Engine Company.

J. A. Fay & Co.'s Wood-Working Machinery; Bement & Sons' Machinists' Tools; Blake Steam Pumps; Knowles Steam Pumps; N. Y. Belting and Packing Co.'s Rubber Goods; Surtreant Blowers and Exhaust Fan; Tanite Co.'s Emery Wheels and Machinery; Payne's Vertical Engines and Boilers; Perry's Centrifugal Pump; Judson's Standard Governors; Dreyfus Self-Clutch; Gould Mfg. Co.'s Hand and Power Pumps; Ellipse Windmills; Disston & Sons Circular Saws; Otto Silent Gas Engine; Duca's Elevator Cups; Ballard's Oak Tanned Belting. Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

W. T. GARRATT'S

BRASS and BELL FOUNDRY
SAN FRANCISCO.

MANUFACTURER AND IMPORTER OF

Church and Steamboat BELLS and GONGS
BRASS CASTINGS of all kinds,
WATER GATES, GAS GATES,
FIRE HYDRANTS,
DOCK HYDRANTS,
GARDEN HYDRANTS

General Assortment of Engineers' Findings

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice free. Address, **DEWEY & CO.,** Office MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, 202 Sansome Street, S. F.—1879.

SAN FRANCISCO, May 25, 1880.
Messrs. DEWEY & Co.—GENTLEMEN:—In acknowledging receipt of my two patents, I desire to express my thanks for the prompt attention which my business has received. The successful manner in which you have conducted the same shows a marked ability as Patent Agents, and I shall take pleasure in recommending your firm to all who desire to obtain patents. I have received copies of the MINING AND SCIENTIFIC PRESS containing descriptions of my inventions. With the best of wishes, I remain,
Yours truly, Louie Bronson.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, Its Formation and History." This
very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing sec-
tions, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & Co., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. STEARNS will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretensions claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - San Francisco, Cal.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it in the reach of all, and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is, is a most important improvement in the working of gold ore, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over all other Steel Castings. Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, sash, Mulay, jig, drag, circular, cylinder and hand Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, sawing, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,
624, 626 and 628 Market Street, Philadelphia

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal. It is with pleasure that we publish the following from prominent Architects in this city: Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Huernic, John Marquis, E. McDougal & Son, Wm. Mosser, Wm. Curlett, Meeker & Banks, W. C. Hoagland, S. & J. Newson, B. VOLUME XLII
Number 4.

Accidents on British and American Railroads.

The management of railroads in this country is generally believed to be so reckless, and the accidents on them resulting in death or injury are so frequent, that few persons would accept without hesitation the statement that for a given year, the accidents of this class in Great Britain were largely in excess of those in this country. Yet the record shows this to be the fact. Here are the relative figures from the *Railroad Gazette's* systematic record: Great Britain, for 1879, killed, 1,032; injured, 3,513; total, 4,545. United States, from May 1, 1879, to April 30, 1880, killed, 180; injured, 647; total, 827. In reviewing the tables of accidents for Great Britain in 1879, the *Iron Age* states that the British returns of accidents on railroads are more complete, and, therefore, more trustworthy than ours; nearly or quite every accident in the Kingdom appearing in the returns of the Board of Trade, while in the United States many accidents are not noticed at all. Until the reports shall be so rendered by our railroad companies as to embrace every accident, they will not afford trustworthy data on which to base a comparison between the United States and Great Britain on the score of accidents. There is a tendency on the part of American railroad companies to cover up accidents, from the apprehension that their publication would injure the line. This fact, and the denser population of Great Britain, may account in part for the difference in the number of accidents as above reported.

The *Iron Age* calls attention to another feature of the report of accidents on British railways for the year 1879; and, that is, the high percentage of accidents connected with the track, and their greater fatality. The following table, giving the total number of persons killed and injured in the United Kingdom for the year 1879, will show this:

Classification.	Killed.	Injured.
Passengers:		
By accidents to trains, rolling stock, permanent way, etc.	75	602
By accidents from other causes.	85	705

By accidents to trains, rolling stock, permanent way, etc.	8	118
By accidents from other causes.	444	1,833
Persons passing over railways at level crossings.	64	30
Trespassers (including suicides).	308	137
Other persons not coming within above classifications.	48	88
Total.	1,032	3,513

Of the entire 1,032 killed, 308, or a little less than 30%, were trespassers on the line, while of the 3,513 injured, but 137, or less than 4%, were of this class. The only other case in this table in which the killed by any one class of accidents exceeds the injured is of persons passing over railways at level crossings—30 being injured and 64 killed. In another table the same is shown as to passing over lines at stations—24 being killed and 11 injured. In a table giving the oc-

cupations of the servants of the company killed and injured, the only occupation in which the number of killed and injured approach each other is among the permanent way men—103 being killed and 156 injured. This 103 is 33% of all the killed, while the 156 is a little over 10% of the injured.

These figures are full of instruction to our railroad companies, and ought to receive careful study and analysis. They indicate certainly the direction in which greater care should be exercised and more complete safe-guards used. The number killed of the servants of companies, who are designated "permanent way men," is something enormous—33% of the total number killed in the year. It would appear that such a remarkable result must arise either from the extra-hazardous occupation of the men, or from the low order of intelligence of the class from which they are recruited. In any view of it, a

Niles' Hoisting Engine.

Our engraving on this page illustrates one of Niles' double-reel geared hoists, and consists of a pair of 12 by 18 inob engines, link motion, style known as Corliss pattern, bolted at each end on cast-iron sole plates, extending from one engine to the other; crank shaft made from the best hammered iron and fitted with a heavy fly-wheel in the center. Two pinions, with clutches to the crank shaft, that bring the pinions into action whenever desired. The reel and spur gear are strongly bolted together. A very effective arrangement of brakes is secured by setting heavy wooden friction blocks in wrought-iron frames, which are carried below, fitted in sliding boxes resting on sole plates and

Placer County Mines.

The hydraulic mines around Dutch Flat all have an abundant supply of water and are doing well. The prospecting work going on in the vicinity is giving encouraging results, and several promising claims are being developed. The water supply of the hydraulic mines on the Forest Hill Divide is giving out. The Dardanelles is piping for a few hours daily with 2,000 inches. The other hydraulic mines are doing little or nothing. The Hidden Treasure, at Sunny South, and the Breese & Wheeler, at Bath are working with a full force of men. The latter is yielding net about \$15,000 monthly. All of the more prominent quartz mines in the county, with the exception of the St. Pat-

rick, at Ophir, which has temporarily ebbed down, are doing well.

At the Conrade mine on Duncan Hill, the shaft has been sunk to a depth of 100 ft. The ore at this depth is very good. The east drift on the 75-ft. level is in 55 ft. running in high grade ore. A whim has just been put up, and other permanent improvements made. Eighty-five tons of ore taken out in the shaft, and in opening the 75-ft. level has yielded \$4,100, an average of \$48 a ton.

At the Shurtleff mine ore has been stopped out between the two shafts 40 ft. apart and 80 ft. deep, the vein averaging 24 inches in thickness. Thirty-six tons of this rock crushed yielded \$8,500, or an average of \$236 a ton. Fifty tons of equally rich ore are on the dump now. Mr. Shurtleff is having a whim erected, when the shaft will be deepened to about 200

ft. He also contemplates erecting a mill at an early date.

Operations at the Iron mine are being pushed forward rapidly. The furnace is fast being completed, and within 60 days it will probably be in blast. A reservoir of a capacity of 6,000,000 gallons is being constructed to supply the water needed for the hydraulic machinery and boilers.

A VALUABLE MINE.—The Victorine mine, lying in the mountains flanked on the west by Smoky valley, in eastern Nevada, which has been idle for many years, is likely to prove a very valuable mine. The correspondent of the *Eureka Sentinel* says that lately Mr. Edward S. Stokes, who owns the mine, sent into Austin a piece of Victorine ore weighing some 75 lbs.—a splendid mass of gold-bearing quartz—the assay value of which was \$960 in gold and \$67 in silver per ton. The owner has been exploring for the vein of the Victorine for several months, and has cut it at last while sinking a winze. Its dimensions have not yet been ascertained; but the vein is believed to be large, as the outcroppings, which were cut years ago, were remarkably bold. It now seems probable that the Victorine will redeem its original promise.

E. L. Bradley, formerly State Senator from Placer county, died in San Jose, July 17th, from the bite of a kitten.

NILES' DOUBLE-REEL GEARED HOISTING ENGINE.

permanent way man must be a "dreadful trade."

A WORD OF CAUTION.—A correspondent at Dutch Flat, Placer county, has written to us in relation to a description of the St. George gold gravel mine, published in the *Mining News*, of New York. He questions the accuracy of many of the statements in the publication, and directs attention to the omission of specific information as to the locality of the property, neither township, district, nor county being mentioned. He adds, also, that in his belief there has never been an official survey by the Government of the ancient river channels of California; and that the only work of that kind is a small diagram, published in 1877 by the U. S. Mining Commissioner. This diagram was compiled by C. J. Brown, of Dutch Flat, who gave permission for its publication; and our correspondent, who is evidently familiar with the subject, alleges that he did the field work, collated the material and originated the theory embraced in that diagram. But it was not official. At present we have no time to verify the facts at issue. We think it well, however, to advise those who may wish to invest in the mine specified, to first get at all the facts relating to it, which they may do by addressing Andrew Larson, Dutch Flat, Placer county, Cal.

connected with heavy wrought-iron rods on the top; they are applied both to fly and brake wheel, by the engineer, through suitable foot levers. Messrs. Parke & Lacy are prepared to furnish the following sizes at short notice: 8 by 12 inch engines, drums 48 by 28 inches, weight, 15,000 lbs.; 10 by 12 inch engines, drums 48 by 28 inches, weight, 18,000 lbs.; 12 by 18 inch engines, drums 66 by 30 inches, weight, 40,000 lbs. Address Parke & Lacy, Nos. 21 and 23 Fremont street, in this city, from whom all information can be obtained.

PASS OF THE CASCADES.—The party of engineers of the Northern Pacific railroad which went to examine the Natchess pass of the Cascade mountains, has reported that the summit was crossed about 40 miles southeast from Wilkeson at an altitude of about 4,800 ft. The ascent from the west side is easy until the backbone is reached near the summit, at which point a tunnel about one mile long will be required. The descent into Yakima valley is said to be much superior to the approach from the west. The report of the engineer in charge of the party, Mr. J. T. Sheets, is represented to be favorable beyond expectation. The condition of the pass, it is said, removes all apprehension of difficulty from snow; and the location is fortunate in other respects, as it secures a direct line on the eastern slope of the Cascades from Ainsworth to the Sound.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

El Dorado County Notes.

EDITORS PRESS:—Since writing you last I have visited many of the mines in El Dorado Co. At the Rosserans mine a 10-stamp mill is running day and night; the ore is prospecting well, and the ledge is of substantial width. The Taylor mine, owned by L. B. Mastick, Col. Nelson and other parties, of San Francisco, is not being worked, although the 10-stamp mill which was run successfully so long is still on the ground. The trouble with this mine is, that while it is for sale, the proprietors are injudiciously asking a fabulous price for it, unwilling to take what is reasonable. And right here I wish to say that this custom is much too prevalent in El Dorado Co. Owners of mines scare away capitalists who are looking for mines in California by demanding unreasonable prices for their property, under the impression that because these rich mines are located so conveniently, amid wood and water, and where the advantages of cheap transportation are available, and where cheap labor is so easily procured, that therefore capital cannot avoid investment here. The consequence is, capitalists do not so much as inquire into or investigate the quality or quantity of our rich ores, and the miner who has discovered and located valuable quartz ledges in El Dorado Co., and who could, if he were judicious, be independent in a day, remains a poor man, and sits at ease, "waiting for something to turn up."

There is another unfavorable feature of the case which has repeatedly come under my observation here. Owners of mines which are for sale are in the habit of giving every other mine in the neighborhood but their own a "black eye," as the term goes. I have myself visited mines which are known to yield well and to be good property, and have afterwards inquired of owners of neighboring mines as to the value or prospect of such mines, with the pretended view of purchasing, and I was certain to hear nothing but disfavor concerning them. No mine in the neighborhood was good but their own. It is easily seen how disastrously this must work to the interests of all; for as soon as the "grand round" of the working mines and prospected ledges is made by would-be purchasers, the reputation of the entire region is seriously injured, if not ruined. The cause of this, probably, is, that almost all mines are for sale, because the owners are comparatively poor, and stand in urgent need of coin. But while they are anxious to sell their mines, they are doing just what is calculated to retard their sale. I have written thus in the hope that the mine-owners of El Dorado Co. may know how the case is viewed by a disinterested looker-on, and may improve by the suggestions implied in these statements.

At Spanish Dry Diggings Mr. Lewis Sites has tumbled upon exceedingly rich prospects. From a decomposed porphyritic rock he is panning out all the way from 25 cents to \$75 the pan. It is called the Modoc mine, and seems, so far as present appearances go, to be exhaustless. It adjoins the well-known Pennsylvania mine on the east. We are pleased to learn of this rich "strike" of Mr. Sites, for he is one of El Dorado county's very best and most worthy men.

The "Golden State" mine, three miles from the above, is also yielding well, as are also several "diggings" in Onion valley, owned by Messrs. Chessrown and Edwards.

The Lady Emma, at Kelsey, is about to be reopened, and the company will soon erect a mill on it.

At Placerville are located many rich mines, as the reader is aware—among them the Pacific, near town, where a 20-stamp mill is in perpetual motion, crushing rock which pays \$10 to the ton, and the Gross mine, where immensely rich rock has been struck. A drift is being run in the Gross mine to ascertain the extent of the deposit. In Coon Hollow the Weber mine has reached the shaft in the old mine, and prospecting has begun in earnest. A citizen of Placerville, named Pierre Vignaut, owns a ledge near the Gross mine, on which he has cross-cut 13 ft., showing gold all the way.

During my stay in Georgetown I had the pleasure of meeting Mr. Thos. Findley, managing director of the California water and mining company. Through the courtesy of this gentleman I was invited to visit the Nagler mine at Greenwood, the property of this company. This is probably the richest mine in the State. It is hydraulized to a depth of from 40 to 70 ft., and averaging 500 ft. in width. Several millions of dollars have been taken out of this mine by former owners. The rock is serpentine and talcose slate, greatly decomposed. A shaft of 150 ft. has been sunk, the lode widening as the shaft descends. Two hundred thousand tons of rock lie on the dump ready for crushing as soon as the 30-stamp mill, which the company is erecting, can be put in operation.

In my next I will speak of other mines I have visited in this section. A. J. B.
Placerville, Cal., July 8, 1880.

Silver Mines in Eastern Nevada.

An Account of the Famous Alexander Mine, Grantsville, Nye County.

Mr. Samuel T. Curtis, Superintendent of the Justice Co., having recently made a visit of observation to Grantsville, has given the following interesting account of its principal mines, and of the mining facilities of the district, to the *Territorial Enterprise*:

Grantsville

Is a very promising mining camp of about 700 people. It is 70 miles south of Austin, the present terminus of the Central Nevada narrow-gauge railroad. The town is situated on a flat immediately southeast of the canyon, on the sides of which are the Alexander, Brooklyn, Alameda and other mines. Great activity is now being shown in building. Wood is cheap—\$3.50 per cord, for nut pine—and clear, cold water is obtained by sinking wells about 60 ft.

The Alexander Mine.

The main source of support to the town is the Alexander mine, which, in my opinion, is going to be, in a very short time, one of the greatest bullion-producing mines on the coast, if not the greatest. This mine has now in sight one of the largest bodies of ore it has ever been my lot to see, millions of tons of ore in reserves being exposed by numerous tunnels, open cuts and winzes. The mine lays on the north side of the canyon, and five tunnels or openings have been made, disclosing ore bodies of great magnitudes. In one open cut, where the ledges crops to the surface, the ore is being quarried about 25 ft. deep, and looks as if the body was inexhaustible.

The upper ores are chloride, and the character of the ore changes to sulphurets in depth. No. 5 tunnel is on a level with the bed of the canyon; the level is only partially exposed yet. One body on this level has been cut into over 80 ft. of solid sulphuretted ore, and another very fine body of chloride and sulphuretted ore mixed has been penetrated a considerable distance. From small tunnels, shafts and other openings it is shown to a certainty the ore body extends to the extreme ends of the claim and to the croppings on the apex of the hill. No. 6 level is opened by incline shaft, and is over 70 ft. below the level of the ravine and water level; shows very fine sulphuretted ore. Work has only been commenced on this level, and crosscuts have not reached far enough to cut the ore bodies of the level above, but enough is now seen to prove that it will be a great level. In all the openings in the mine from the surface down there are immense reserves, the work in the mine being carried on by small stopes at great distances apart in the large ore bodies, and as the rock stands well, sufficient ore is obtained in this manner, with little timbering, to keep the mill running.

The mill has 20 stamps, crushing dry and using White & Howell's roasters. A well sunk inside the mill supplies the water, and this well, although a considerable distance south from the present workings, has penetrated the ledge on its dip, the bottom being in good sulphuretted ore. The rock is not very high grade, but wood is cheap (\$3.50 per cord at the mill), and facilities for mining are so good that the low cost of extraction and reduction make an equivalent.

Yard-Stick Superintendents.

This mine gives another example of the sagacity of Eastern yard-stick Superintendents. The property once belonged to an Eastern company, and under such direction the first act was to build an expensive mill in the valley about 10 miles from the mine. A little ore was worked and failed to pay. A long tunnel was run and found nothing, for the simple reason that it was run parallel with the ledge. The mill was torn down and removed to White Pine during the excitement at that place.

The mining ground lay abandoned for years, until it was relocated and finally came into the hands of the present managers. Supt. San Pedro ran a crosscut from the long tunnel run by the Eastern folks, and in a few feet struck ore. Two mills were immediately furnished, and rock averaging about \$70 was found. Some time afterwards a company mill was erected of 20 stamps, and bullion has been flowing steadily since, the last month's product being about \$45,000. Twenty stamps more are being added to the mill at present, which will increase the yield two fold, with very little increase of expenditure.

Other Good Mines.

There are several very fine prospects in the camp outside the Alexander. The Brooklyn, Alameda, Lloyd and Mollie Brinton are in shape to pay. The Brooklyn shows a large body of ore, \$37,000 being produced from this mine last month, the ore worked averaging something over \$70 per ton. The McMahon, belonging to a Chicago company, has struck a good body of ore in their shaft. The Natchez, Galatea, Chicago, Oriental, Cadiz, Brooklyn No. 2, Potosi, Leffer tunnel and the Triumph Con. company are all promising properties, and prospecting is so active in camp at present that new discoveries may be made shortly.

The San Pedro District.

About 20 miles northwest of Grantsville, contains many large ledges and an abundance of wood and plenty of water for milling purposes.

The Belle District.

About 40 miles west, contains some very fine ledges, but wood, with the exception of cedar, is scarce.

Ellsworth District.

About 17 miles further on, shows very many

fine ledges, most of them large and, as far as developed, producing rich ore. Wood is very plentiful and water easily obtained. Here again is another Eastern mill rattling down in charge of a keeper.

In the valley near Ione is still another mill built by Eastern folks for the Ione property on the site of the old mill erected for the Alexander mine years ago. This mill is idle and afflicted with the same troubles as all its Eastern brethren in this section, past and present.

A Contribution to Californian Geology.

Paper read before the California State Geological Society by Melville Attwood.

Mr. I. Beetes Jukes, in his very useful and truly practical "Students' Manual of Geology"—which ought to be read by all engaged in mining—says, in his introduction to the subject:

In order to reduce the great subject of geology to something like order, it appears advisable to divide it into three heads, for which we use the terms of, 1. Geognosy; 2. Paleontology; 3. The history of the formation of the series of stratified rocks. By geognosy, I would understand, then, the study of the structure of rocks, independently of their arrangement, into a chronological series, and I would divide it into two parts—lithology (stone lore) and petrology (rock lore). By lithology, I would mean the study of the internal structure, the mineralogical composition, the texture and other characters of rocks, such as could be determined in the closest by the aid of hand specimens.

Under petrology, I would arrange the larger characteristics of rocks, the study of rock masses, their planes of division, their forms, their positions and mutual relations, and other characters that can only be studied in "the field," but without entering on the question of the geological time of their production.

Under the head of paleontology, I should wish to give the heads of several great questions as to the laws which have governed the distribution of life, both in space and in time, as also to indicate some of the chief points in the structure of the more important extinct races and their relations to those now living.

"Jointed Structure."

All rocks, eruptive, sedimentary and metamorphic, are traversed by numerous planes of division termed "joints," obviously the natural result of the shrinkage or contraction of the rock masses during consolidation.

In studying the stratified rock it will be seen that, besides the planes of division, the result of succession in the acts of deposition, and which form separate strata or beds, there are other planes of division ("joints") which intersect the beds at various angles. It is not uncommon for these joints to change their angle in passing from one bed or stratum to another. Joints are mostly regular and close in proportion to the compactness of the texture of the rock; in sandstones they are uneven and often open.

In volcanic rocks the joints have been, in many cases, widened by the action of water percolating through them and dissolving a portion of the rock. Little or no attention appears to have been paid to the jointed structure of the enclosing rocks of the Comstock lode; the general direction or course the planes of jointing in Comstock rocks are nearly the same as that of the lode, and their dip and the underlay of the lode and ore bodies have a corresponding angle of inclination. A careful examination of the jointing of the rock east of the lode would enable a petrologist to distinguish the dykes from the sheet rock. The prismatic joints, like those in the basalt at the Giants' Causeway, which often resemble dry starch in their irregular and wrinkled sides, are too well known to say anything about them. The joints in granite enable the quarryman to carry on his work with success; indeed, the whole art of quarrying consists in taking advantage of the natural divisions of the rocks by joints.

I have made a careful examination of the "jointed structure" from the Aurora Tunnel to Bodie Bluff, and found that in that section the joints, or rents, form planes of separation which are often slightly open and from a few inches to many feet apart. They traverse the rocks in straight and well-determined lines, which have definite compass bearings. They appear to be of three kinds—"vertical joints," "dip joints" and "diagonal joints." The crevice veins filling portions of these joints, or rents, are mostly of a limited extent and depth, though sometimes rich in gold.

On Bodie Bluff the croppings of many veins of this character may be seen; they are similar to what are termed "gash veins," being wedge-shaped and terminating at no inconsiderable depth. Others, however, are very different, though of the same class, like many of those met with to the south of the Standard mine, which are rich in gold, but do not appear to have any croppings, and have been discovered by crosscutting at some depth below the surface of the ground, filling portions of the dip joints and following them down till intersected by diagonal joints, and running along the diagonal ones into other dip joints.

A similar class of auriferous veins has been met with in Australia. Mr. Daintree, F. G. S., says, in a paper which he read before the London Geological Society, in 1878, "On certain modes of occurrence of gold in Australia." Below the zone of decomposition, however, we generally lose a class of auriferous veins which have proved very misleading to the miner, though usually very rich in gold. These usually

follow the line of jointings in the rock, and are, in my opinion, simply due to the decomposition of this auriferous pyrites and of the country rock, and the redeposit of such of the decomposed material as passed into chemical solution in local fissures. The Bodie rocks are of the same class as those met with to the east of the Comstock, and overlying that lode, the greater proportion of which may be called "fracture dikes," in all their different stages of alteration and decomposition—diorite being employed for the old term greenstone. Mr. Rutley, in his valuable little work on "The Study of Rocks," says: "The term 'greenstone,' which, in its older signification, embraced basalt, diabass, gabbro, diorite, etc., has subsequently been restricted in its application, and employed as a synonym for diorite. Since, however, the name greenstone is almost meaningless, it seems desirable either to discard it, or, still better, to use it in its original sense as an ambiguous and comprehensive term, useful in field geology, but otherwise only admissible as an expression of comparative ignorance, such as may safely be employed in the case of rocks of a certain type, which have reached so advanced a stage of decomposition, and in which the constituent minerals are so poorly developed, that it is no longer safe or possible to hazard any opinion concerning their precise normal mineralogical constitution." The rocks collected during the sinking of the new Yellow Jacket shaft—now, I believe, some 3,000 ft. deep—will, when properly determined, throw more light on the geology of the Comstock than any work that has yet been undertaken.

The difference between the Comstock lode and the lodes of Bodie—I mean those of the Bodie lodes which occupy portions of fissures which have dislocated and displaced the jointed structure—is that the country east of the Comstock lode forming the hanging wall, consists entirely of acid rocks (rocks containing a large proportion of silica), while the west country's footwall rocks are what are called basic rocks—andesite, dolerite and Mount Davidson diorite—all of which contain but a small percentage of silica.

The branch fissures, however, which yielded such immensely rich ore bodies, have jointed structure to the east and west of them, and are enclosed in acid rocks, so that it is comparatively easy to distinguish between them and the main lode.

The Bodie lodes, so far as I have examined them, have acid rocks for their foot and hanging walls; in fact, are enclosed in them.

The most reasonable solution for the hot water encountered in the deep workings of the Comstock, is that of "expiring volcanic action," and the high temperature of the east country rocks, or those overlying the lode, I think is caused by the heated vapors rising from the main fissure through the planes of the jointed structure and numerous branch fissures, the west country rocks being comparatively cool.

Hot springs are nearly always found in the neighborhood of extinct and active volcanoes. "We learn from Bunsen's experiments on the great geyser in Iceland, that at the depth of only 74 ft., at the bottom of the tube, a column of water may be in a state of rest, and yet possess a heat of 120° centigrade, or 248° Fahr." Those who can remember the Steamboat springs in Nevada and the Geysers in Lake county 20 years ago, can realize how rapidly the volcanic action is subsiding.

In M. Truher and Margolli's book on "Volcanoes," the Steamboat springs are described as follows: "We have already described the intermittent springs of Iceland—the Geysers—similar springs have been discovered in California, on the eastern slope of the chain of Sierra Nevada, not far from the Lake of Washoe. The water rises in jets to a height of seven yards; the jets follow each other at intervals of five minutes, and produce a noise which resembles thunder."

The temperature of the hot water met with in the Clifford amalgamated mines, Cornwall, closely corresponds with that of the Comstock. (See report, 1864, of Prof. W. W. Smyth, Chief Inspector of Coronado mines.) At a depth of 1,350 ft. below the adit, or 1,650 ft. from the surface, the water issued at a temperature of 122°. The enclosing rocks of the Wheel Clifford lodes are clay, slate and quartz porphyry, both of compact texture.

RECKLESS BRIDGE BUILDING.—Many railroad companies in building wooden bridges take no pains to get iron rods which are suitable for such work, but purchase what is easiest to be had in the market, and in many cases never find that the iron was bad until a bridge tumbles down. There are without the slightest question, hundreds of bridges now in use in this country, which as far as mere proportions and dimensions go would appear to be entirely safe, but which on account of the quality of the iron with which they are made are entirely unsafe; and there always will be as long as railway presidents, superintendents or roadmasters buy iron which they know nothing about, to put into bridges.

EXPLORING BOYS.—Colorado Springs has a "Boys Exploring Association," organized and conducted by Rev. R. T. Cross, of the Congregational church. "The object of this association is to carry on explorations in the vicinity of Colorado Springs, and to secure physical, mental and moral improvement." On the first trip, two of the boys discovered in Williams canyon what is declared to be the finest cave in the State. It is not yet fully explored, but has many chambers, and wonderful stalactites.

MECHANICAL PROGRESS.

American vs. English Railroad Engineering.

R. M. Brereton, engineer-in-chief of the Great India Peninsular railway, writes from England to W. W. Evans, of New York, as follows: During the past 26 years I have spent 14 years in India in the construction and working of one of the principal guaranteed railways, besides four years in England, and nearly eight in the United States, so that I am able to compare the working results in each country from the standpoint of experience. I have come to the conclusion that we can and ought to construct, equip and work our railway system in India, in our several colonies and in this country, too, in a far more economical manner than past experience here has shown to be possible, or our consulting engineers, managing directors and agents (who have not had the opportunity of studying the working of the 77,470 miles of railway of the United States) have hitherto believed to be possible.

In regard to locomotives, the Americans certainly obtain from 8,000 to 10,000 train miles greater duty per annum than we can in this country or in India, and this, too, under the following drawbacks: Inferior road-beds, steeper gradients, sharper curves, more severe climate, heavier loads hauled and less speed in running. The greater duty obtained cannot be due to better workmanship and superior materials, because it is well known that the English mechanic in skill of hand cannot be excelled, and the very best materials are employed by our English builders, and the hours of work in both countries are nearly the same. Hence, I argue that the greater duty done by the American motor is due to the better design and the better system of working the locomotives. The American builder excels in the system of framing and counterbalancing, and in the designs of the crank, axles, etc., so that the engine may run remarkably easy and without jar around sharp curves, and work not only on the light roads, but also diminish the wear and tear on the solid roads, and at the same time increase the effective tractive force. The English engine is a very heavy affair, and, in running, it not only wears and tears itself very rapidly, but also the roadway, and it greatly, by its unsteadiness and jar, fatigues the drivers and firemen.

NOVELTY IN WIRE ROPE.—A method is being employed by Messrs. Cradock & Co., of Wakefield, of manufacturing wire rope, which they thus explain: "By the old or ordinary mode of construction of wire ropes, the wires are worn on the crown of the strands, whereby friction is confined to a very small portion of the wire only; the wires in a rope are almost in a straight line with the rope, and as they retain their full size and strength on each side of the worn or weakened part, the working of the rope around drums, pulleys and curves causes the bending to take place on the worn or weakened part especially; hence, the reason why so many ropes have to be thrown aside as useless, through breaking of wires when but slightly worn." They further state that by their improvement in the construction of round and flat ropes, they have a much longer surface of the wire exposed to friction, and, less, if not entirely remove the cause of wires breaking on the crown of the strands. As the working of the rope around drums, pulleys and curved heads the wires in an oblique direction, they thereby secure the greatest amount of wear from the wire that is possible, as the wires will not break until they become too much reduced in strength, and therefore too weak for their work. The wires in the strands, on this principle, it is asserted, have a very much longer hearing one against another than in the ordinary system, and they are thereby enabled to prevent the great injury resulting from the wires in each adjoining strand cutting into each other. They therefore claim for this new rope a greater durability than can be obtained by any other construction. We are sure that colliery proprietors and others using such appliances will give due consideration to the claims put forth by the manufacturers.

CHERRY HEAT WELDING COMPOUND.—This compound is comparatively a new thing, and is designed to supersede borax for welding purposes, and is said to be not only superior to borax, but valuable for many purposes for which borax is useless. Less heat is required in welding for this compound, and, consequently, a considerable saving in time and coal attends its use, enough, the manufacturers of the compound say, to more than cover its cost in many cases. It is also said to be a perfect protection to steel from any degree of heat obtainable in a smith's forge, and by its aid many forgings of steel can be made at one heat, which, without it, would require three or more heats. It is claimed also to possess the quality of restoring "burnt" steel perfectly.

ADVANTAGE OF METALLIC LUBRICANTS.—In a drying machine it was found impossible, even with the greatest care, to keep the rollers clean, so as to prevent the injury of the goods by grease-spots from the lubricating oil. The difficulty was entirely obviated by the use of metailine as a lubricant.—*Chron. Ind.*

Steel Wire.

During the progress of making the cables of the East river bridge, N. Y., and the testing in connection with this work, some interesting experience has been gained as to the strength and characteristics of high class steel wire. According to some data recently communicated by Mr. F. Collingwood to the American Society of Civil Engineers, there can now be had in quantity steel wire having a tensile strain of 160,000 lbs. per square inch, and giving before breaking an elongation of 23% in 100 ft. lengths, or an elongation of 4% when tested in one ft. lengths. Steel of the same quality as that in the above-named wire, when made into bars of the ordinary sizes used in bridge building, has been found to have a tensile strength of 70,000 lbs. to 75,000 lbs. per square inch, with an elastic limit of 40,000 lbs. per square inch, and an elongation of 15% in samples one ft. long. As regards the wire, the experience at the East river bridge has shown that with steel wire drawn and coiled in the ordinary way, no satisfactory determination of the elastic limit or of the elongation before fracture can be made, on account of the set induced by coiling. This inconvenience can, however, be avoided by leading the wire straight from the galvanizing-trough to such a distance that it becomes cool before it is coiled, at the same time taking care that the coils are not too small. In the case of the East river bridge for wire of No. 7 and No. 8 B. W. G., the diameter of coils used is four ft. six in., and wire so coiled will lay out straight when loosened from the coil. Mr. Collingwood states that galvanizing has been found to increase the strength of freshly drawn wire about 15%, while ungalvanized wire has been found to gain nearly 5% in strength by being simply allowed to rest for a week or two after drawing. The increase of strength in both these cases appears to be due to some adjustment of the strains set up during the drawing process. Galvanized wire has also been found to increase slightly in strength by being allowed to rest.

CORRUGATED BOILER FLUES.—According to Engineering corrugated boiler flues are rapidly coming into favor in England. More than 200 have been delivered by the makers this year, and about 150 are at present in course of construction. By repeated tests it has been shown that these flues are much stronger to resist collapse than ordinary flues of the same size and weight of metal, and it is claimed that they have enabled marine boilers to produce considerably more steam. The fact of their great advantage has been arrived at chiefly by comparing the performance of nearly similar vessels with and without corrugated flues. The former either attain higher speeds or use less fuel, the difference being very marked. Not less important than this radical improvement in boiler construction, is the fact that they have been successfully made out of steel plates, welded by a special machine. The plates are of Siemens-Martin steel, and some are as large as 15 ft. long by 8 ft. 9 inches wide. This welding of these plates into tubes is certainly a noteworthy event in the manipulating of steel. The Leeds forges company, however, are about to construct machinery for rolling solid steel tubes without weld, 4 ft. 9 inches in diameter by 9 ft. long, from seamless circular blooms, under Mr. S. Fox's patents. When a weldless and seamless steel tube of these dimensions can be made, it would seem as if the very perfection of tubemaking had been reached.

THE WEAR OF STEEL RAILS.—The first engineer of the Rhenish railway, which has the longest experience in steel rails, has made a calculation, according to which the average duration of steel rails, where 24 trains pass over them every day, is 30 years, while that of iron rails, with a traffic of 17 trains, is 11 years. Steel rails, according to this calculation, last four times as long as iron rails, although they are but one-third more expensive. According to other experiments made in Germany, it is calculated that the mean duration of rails of Bessemer steel is about 16 years. On the other hand, it appears that 10 years of trial between Boulogne and Minden have shown that the renewals were, during that period, 70.7% for fine grain iron rails, 65.3% for cement steel, 33.3% for puddled steel, and only 3.4% for Bessemer steel, indicating that the latter class of rails would last longer than 16 years. There are, however, some faults to be found with this rail. The engineers of the Kaiser Ferdinand Northern line state that Bessemer steel is less capable of resisting concussion, and that, when sudden friction has caused heating of the rails, with rapid cooling from snow, injurious molecular changes are apt to occur.

WELDING TUBES AND TIRES.—Krupp, the great steel worker of Germany, has recently patented a new method of welding tubes and tires. He draws the tube over one pair of ordinary rolls, and then heats the whole length of the portion to be welded by a special contrivance, which is a portable fire-box, into which air is so blown that the heat is directed against the weld. After the necessary heat is attained, the rolls are set in motion, and the place to be welded is repeatedly drawn through them.

SCIENTIFIC PROGRESS.

The Microscope in Geology.

In no department of natural science has the student heretofore been compelled to tread with more uncertain step than in that of lithology. The interpretation of general geological phenomena has been quite satisfactorily given by Lyell; while the significance of organic remains in the sedimentary rocks has been quite as clearly unfolded by Buffon. But it is only recently that the geologist has been able to study the mineral constituents and minute structures of rocks, so as to decide with any degree of certainty in regard to rock genesis, or rock formation. In past times, if we gave a geologist a piece of rock for examination, he would tell us it was quartz, or granite, or trap, as the case might be. He might, perhaps, tell us it contained some kind of metallic substance, and with the aid of the crucible he would be able to tell us how much of the various metals it contained. But ask him about its mineral structure, how it was built up, the forms, nature and relative condition of its component parts, and he could tell us little or nothing. Through this ignorance of the building up of rocks, great confusion has existed in regard to the whole subject of petrology, and rocks of widely different natures have often been classed by our most learned geologists under the same name. Various methods of investigation had been employed to reach more accurate determinations. The microscope had been brought into requisition in the ordinary way of its use. Chemistry had been invoked, and its searching analysis employed to unveil the secret workings of nature in building up the stony foundations of the earth, but all with little success; and the geologist had about concluded that any further progress in this special department was at an end. Just at this time, Mr. Henry Clifton Sorby, an English geologist, resolved to apply the microscope in a new direction. He took thin scales of various rocks, ground them down into exceedingly thin plates, carefully polished these plates, or sections, on both sides, and mounted them on glass slides for examination, by either transmitted or by polarized light, with the view of determining how much they would thus be able to tell of their own history. He worked patiently for a long time in this direction before he reached any satisfactory results, and it is now only some 10 or 12 years since he was enabled to announce to the world that what the spectrum had done in revealing the composition and condition of the distant stars, the microscope, in his hands, was doing for the rocks and sands under our feet. A new and wide field of research was at once opened up, and great numbers of earnest students availed themselves of the opportunity, until now we are able to study not only the intimate structure of coarse or distinctly crystalline rocks, but also to investigate, with the utmost exactness, even the almost infinitely small crystalline structures, determine the form, nature and position of their granules, study at our leisure the minutest details of their structure, and thus reach most accurate conclusions in regard to their genesis. The microscope is thus becoming not only a great aid, but an indispensable requisite, to the study of geology. It has already thrown a flood of light on a class of rocks that have hitherto been most obscure; it has introduced a system where before all was vague and indefinite—in fact, it has quite revolutionized that branch of geology to which this new mode of study has been applied. By this mode of examination, the observer is often astonished to find that a piece of rock, which to the naked eye, or even when examined in bulk by a powerful glass, seems perfectly uniform—of one color and one type—really contains three, four, and perhaps five or more types. By the study of sections, prepared as above, the mining expert is now far better able than ever before to trace the continuity of either vein or wall rock, and note with certainty the minutest change in the rock through which he is working.—*Science Department in California for August.*

THE LONGEST GEODETIC ARC.—By the joint labors of Spanish and French engineers, under the direction of Ibanez and Perrier, science possesses the measurement of the meridional arc of 27°, the longest that has yet been measured on the earth and projected astronomically in the heavens. Biot and Arago, on their return from Spain, anticipated the possibility of such an undertaking, if the revival of Spanish civilization should ever open the way, and their dream has been realized, after 10 years' work, in an arc which extends from the northernmost of the Shetland isles, in latitude 61°, to the Saharan desert, in latitude 34°, covering nearly one-third of a quadrant.—*Comptes Rendus.*

NEWLY-DISCOVERED NERVOUS ENERGY.—During the past year, Dr. Brown-Sequard has often noticed that the irritation produced by a transverse section of the base of the brain produces opposite effects upon the nerves which are before and behind the section. Following the lead of these indications, he finds that some parts of the nervous system are able, when irritated, to produce a sudden notable augmentation of the properties, or of the motion or sensitive activities, of other parts of the system.—*Comptes Rendus.*

RELATION OF SPECTRAL RAYS TO THE CONSTITUTION OF NEBULÆ.—Ch. Fievey has made the spectral rays of hydrogen and of nitrogen the subject of a special careful investigation. By attaching to the spectroscopic a contrivance which enables him to regulate at will the quantity of light received, he observed that the spectrum of hydrogen was modified and simplified in proportion as the brilliancy diminished. The H line first disappeared, then C, and finally only F was left. It is well to remember that the F line is the only one of the hydrogen lines which has been observed, in a large number of nebulae that have been examined by the spectroscopic. The spectrum of nitrogen gave results similar to that of hydrogen. It is, therefore, not strange that we should meet, in nebular spectra, only the rays which are most persistent in diminished light. Such rays may suffice to establish the presence of the body to which they belong, and the disappearance of the others may be explained by their extinction in traversing the intervening spaces.—*Bull. de l'Acad. Belgique.*

COAL IN INDIA.—Theodore W. H. Hughes begins a paper on the coal fields of India by saying: "It will doubtless surprise many to learn that both in the superficial extent of its coal measures and associated rocks, and in the actual amount of its coal, India is surpassed by few countries, and that with respect to the size of some of the seams it stands pre-eminent in the history of mining." Even the U. S. cannot boast of seams 100 ft., 120 ft. and 160 ft. thick, like some that occur in Bengal. He calculates that the coal fields of India cover 35,000 square miles, and, according to estimates drawn up by Dr. Oldman, there cannot be less than 20,000,000,000 tons of coal in the empire. Much of the material, however, is of an inferior quality and fit only for very rough use.—*L'Ingen. Univ.*

PHOSPHORESCENCE OF THE GLOW-WORM.—WHAT IT IS.—Joussot de Bellesme has repeated the experiments of Matteucci upon the glow-worm with some precautions which lead him to more satisfactory results. He removed the cephalic ganglia so as to destroy all voluntary phosphorescence, and substituted the passage of a moderate electric current through the body, or in the luminous organ, thus producing a brilliant phosphorescence. When the insect thus prepared was plunged into carbonic acid, or into either of the inert gases, nitrogen and hydrogen, the electric excitement produced no light. His investigations lead him to regard phosphorescence as a general property of protoplasm, consisting in a disengagement of phosphureted hydrogen.—*Comptes Rendus.*

AMERICAN LAUREATES OF THE FRENCH ACADEMY.—At the last public annual session of the French Academy the Lalande prize was awarded to Prof. C. F. H. Peters, of Clinton, N. Y., for his planetary discoveries. The total number of asteroids discovered by him is 43, eight of which were added to the list during the past year. At the same sitting the Valz prize was awarded to M. Trouvelot, of Cambridge, Mass., whose magnificent drawings of the planets Mars, Jupiter and Saturn represent the telescopic appearances with remarkable accuracy, and furnish an excellent basis for the minute study of the superficial phenomena of these planets.—*Comptes Rendus.*

THE INDESTRUCTIBILITY OF MATTER.—This is capable of ready demonstration by preparing a couple of glass tubes of equal weight, each being filled with pure oxygen, and containing a few particles of carbon, free from appreciable amount of ash; that prepared from the fine loaf sugar gives very good results. The tubes are of precisely equal weight, and are hermetically sealed. By heating one of them the charcoal is caused to burn, and ultimately to disappear; the tube and contents, however, is of course found still to balance the other tube (which has not been heated), being of precisely the same weight as it was at first.

INFLUENCE OF CAPILLARITY UPON DYEING.—Gustav Engel has conducted an interesting series of experiments upon animal and vegetable substances, with a view to ascertain the principles involved in dyeing. Microscopical examination of infusorial earth showed that the coloring matter was attached solely to the interior capillary tubes. The experiments all agreed in proving that the facility of absorbing and retaining dyes depends almost entirely upon physical structure and especially on capillarity.—*Bull. de la Soc. de Mulhouse.*

NEW THEORY OF THE FORMATION OF HAIL.—Colladon supposes that the heavy rains and the hail-storms which follow them produce, by the very effect of their fall, a vertical wind due to the air which they draw from the upper regions of the atmosphere by their own friction. This vertical wind, which extends from the cloud to the ground, necessarily leaves behind it a partial vacuum, which produces an influx of air during the whole continuance of the storm.—*Les Mondes.*

NEW USE OF NICKEL.—Nickel is more fusible than iron, more malleable, more ductile, tougher and not affected by atmospheric influences. M. Fleitmann has found that when melted it absorbs some carbonic acid, and if a small quantity of magnesium is then added the metal becomes remarkably ductile and malleable. It can be drawn out into very fine wire or beaten into extremely thin leaves, and can be readily welded either to nickel or to iron.—*Chron. Ind.*

The Mining Share Market.

The mining share market remains as it was. The business of the past week was so similar in nearly all respects to that of the preceding week, that a report of its transactions might be embraced in the single word ditto. There were little oscillations one day followed by counter little oscillations the next day, and at the end of the week things were as they were at the beginning. The business begins to have a comic look; for, notwithstanding the queer condition of the market, the hope in the future of both holders and operators is palpable. If their reward shall be commensurate with their hopeful patience, it will be great indeed. At the mines work continues to be carried on with the energy corresponding to its system and magnitude. The engineers of the Comstock are contending with intense heat and vast volumes of water, and there is no reasonable doubt that they will overcome both. Indeed, the matter of ventilation may be said to be already well in hand. The far greater difficulty of controlling and disposing of the water will require more time and labor; but that it will be controlled, so that explorations may be prosecuted to the final development of ore bodies in the lower works of several mines, is the belief of many experienced mining engineers.

Surveys Recommended.

At the regular quarterly meeting of the Chamber of Commerce, held on the 20th inst., the following important resolutions were adopted: Resolved, That this Chamber hereby calls the attention of our Senators and members of Congress to the great usefulness of the United States topographical and geographical surveys of States and Territories west of the 100th meridian, as prosecuted by the Army Corps of Engineers, in charge of Capt. Geo. M. Wheeler, under the direction of Gen. A. Humphreys, and earnestly recommends that our delegation in Congress advocate, urge and vote for liberal appropriations for a continuance of said surveys in the interest of inter-State commerce and the protection of frontier settlements from Indian depredations, and as furnishing a safe guide to immigrants seeking homes in the West, as well as a reliable source of information to capital and enterprise disposed to develop new lines of travel and new fields of production. Caleb T. Fay, after some remarks upon the importance of the Alaska trade and the necessity for full preparations for navigation along the coast, especially referring to the Alaska coast, offered the following, which was also adopted: Resolved, That our Senators and members upon the Pacific coast be earnestly invited to work actively in securing an ample appropriation from Congress for the perfecting of a marine survey of the entire coast and the early issuance of complete maps and marine charts for the safe guide of movements in these waters.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments: Paradise, July 16, \$4,186; Bodie, July 18, \$3,239; Northern Belle, July 18, \$12,346.94; Star, July 19, \$3,285. At Salt Lake City, July 11th to July 17th, inclusive: Horn Silver, \$127,500; Ontario, \$40,064. Christy, \$3,475.04; Barbet & Walker, \$6,175.23; miscellaneous, \$40,394; total, \$177,214.23. Desiring to make our list of Bullion Shipments as complete as possible, we will be thankful to receive from mining Superintendents and Secretaries notice of all bullion shipments from their respective mines. STRIKING REDUCED TO AN ART.—It seems, says the Railroad Gazette, that striking for higher pay has been reduced to an art. The other day a lot of track men on the Illinois Central road, in Iowa, engaged in replacing iron rails with steel, are said to have gained their end by first taking up about 1,000 ft. of track and then striking. Passenger trains were delayed seven or eight hours by this performance, and if the strikers had been arrested for obstructing the mails they would have been served right. Men have a legal right to quit work if they think they are not paid enough, but they have no right to do it in a way intended to damage the public. MEXICO has established a Government Bank, putting about \$600,000 of its notes in circulation.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR. AMADOR CITY NOTES.—Dispatch, July 17: The Keystone company is engaged in the work of putting in new timbers and otherwise repairing their mill. The B

of the Squaw Hollow lead has been found and traced from the North to the Middle Fork of the Cosumnes. The ledge averages 30 ft in width, and is the same composition as that found at the Gross mine.

HASTON CREEK PLUM.—*Mountain Democrat*, July 17: Work has been resumed in earnest on this mine. The completion of this mine will have the town by better drainage than heretofore, and will enable the mine owners on Cedar and Spanish ravines to resume hydraulic mining.

ITEM.—The Chinamen, working in the cut at Morey's foundry, struck a rich streak recently. One man says a shovel yielded nearly half gold.

GREENWOOD NOTES.—We learn from Mr. Charles Nagler, of Greenwood, that the Gallagher mine is down about 70 ft, and is now being timbered preparatory for active work. The recent strike in this mine continues good.

NEW REDUCTION WORKS.—The Georgetown Divide reduction company is putting up an establishment at Greenwood for reducing sulphurets, assaying and working of gold-bearing ores in general. Prof. G. T. Deetken is the engineer and assayer in charge of the works.

INYO.

MODOC CO.—Independent, July 10: This company is pushing work ahead in the mine with a force of 30 men, under the active superintendence of J. S. Childs and foreman, William E. Smith. The mine is located on the main point of the main body of the ore, however, being in the foot of the West Lookout, 300 level. Wood and coal hauling will commence in a few days, and the furnace will be fired up about Aug. 10th.

DEEP SPRING VALLEY DISTRICT.—*Cor. Independent*, June 29: When I tell you there is a ledge here that will assay thousands of dollars per ton, I am only stating a fact I can prove when called upon. The ledge is not wide—running all the way from 6 inches to 3 ft in width—but much of the ore in the district will average \$150 per ton. There is some talk of Mr. Smith, of Teel's marsh, putting up a 6-stamp mill here this summer. Hickey & Walker built a mill here on credit and paid off their indebtedness in little over a year with its earnings. The facilities are all that could be desired; abundance of water free, with wood in unlimited quantities, and the cost will not exceed \$5 per cord.

MARIPOSA.

COUTLEVILLE NOTES.—*Gazette*, July 17: We learn that the shaft of the Martin & Wallace mine is clear of water, and that the ore is being taken from 2 sources in the mine, which bears the character of rock formerly taken from the mine, and is considered an excellent quality of ore. As soon as sufficient ore is brought to the surface, it is expected a mill will be erected.

FLANAGAN.—This mine has recently furnished its owner with another gold pocket, which it is famous for, and keeps its owner animated with a hope of striking larger and richer ones.

MALVINA.—The Cook Bros. are running a tunnel from Black creek through the mountain, some hundreds of ft, with a view to getting under the Malvina mine, which is expected to be completed some time in October next.

MONO.

LAKE DISTRICT.—*Manumoth City Herald*, July 10: Excellent progress is being made in the besider at tunnel No. 2, it having been advanced 48 ft during the week ending to-day; total length, 932 ft. In tunnel No. 3, 68 ft of headway has been made; total length, 1,132 ft. The upraise from this tunnel has now reached the height of 75 ft, 15 ft having been made during the past week. Considerable fitting up having been necessary in this vertical upraise, including, etc., only 310 tons of ore was sent to mill. Hereafter the quantity will be increased to 75 tons per day. The mill is kept constantly running to its fullest capacity, and in consequence of the many improvements in the application of the water power, it has not been found necessary to use any steam in driving the machinery.

H. L. & M. O. JOINT TUNNEL.—Owing to the breakage of drills, caused by the excessively hard character of the rock, the work was delayed a part of the week, but 14 ft made, giving a total length of 895 ft to date.

HOMER DISTRICT.—*Bodie Free Press*, July 16: We learn that while the towns started on Mill creek are at present dull and uninteresting, there is much honest work doing throughout the mines discovered last fall in advance of the storm. There is a road built up the main canyon, so that machinery and supplies can be hauled almost to the head of it, where the Homer M. & Co.'s operations are located. They have developed ore enough to justify them in erecting reduction works before the winter weather sets in. They are running both east and west crosscuts from the tunnel, on which the work of extension is also resumed. The shaft sinking on the rich Wasatch ledge to the east shows well, and it will be connected with the east crosscut for the purpose of ventilation and ore extraction. It is proposed to erect a 10-stamp mill, with capacity of 20, and run it by water, with which power there is abundant and convenient. Work is brisk and systematic on the May Lundy claim, in the Lake Canyon section of the district, and parties are discussing seriously the necessity of a wagon road up that way from the town of Lundy. There are probably 250 people in all in the district.

NEVADA.

DILLON MIN.—*Transcript*, July 15: This new find below Allison ranch continues to show gold below the surface. A local company of capitalists are negotiating for its purchase, and will proceed to work the claim with a good force of men. The mine is so situated on a hillside as to be easily worked for hundreds of feet without machinery.

MR. AUSTIN.—This company struck the ledge in their 300 level north work before last, and have resumed sinking and will go down 200 ft farther before extracting any ore. Thus they will soon be enabled to work the property on an extensive scale.

EL CAPITAN.—The ledge recently developed in the El Capitán mine on the 200 level, 65 ft south of the incline, has been explored for a distance of 20 ft. It averages about 18 inches in thickness, and is producing some very good-looking ore. The north drift on the same level, which is being pushed to develop the ledge in the Wheel Jane property adjoining, is now in 125 ft.

NOTES.—A. C. Gillespie, of Gold Flat, has recently erected an arastra and hoisting and pumping gear on his quartz claim. The machinery to be run with water from the Idaho ditch. On or about the 20th inst., the Blue Tent M. Co. will begin cleaning out their main ditch. The water will be turned off from it for a period of some 3 weeks.

BANNER HILL MIN.—*Herald*, July 13: It is expected that work will shortly be commenced at this mine. But a small force of men will be employed for the commencement. Machinery will be immediately placed in position, and everything will be in running order in a very short time.

MOHAWK.—This claim is still improving; work is being pushed preparatory to erecting machinery. The west drift is being driven as fast as possible, where a few days since a strike was made which is developing into a fine chute of ore over 3 ft thick, and proves to be good milling ore.

FORTUNA.—Such rapid progress is being made in the sinking of the shaft at this mine, that it is thought that it will be completed by the first of next month, when stations and drifting will be commenced. Some very good rock is at present being taken out.

MUSCHIE.—Work in the new shaft of this mine is progressing favorably. It is expected that it will be completed and the new 30-stamp mill erected and other improvements finished about the month of October.

NOTES.—Rapid progress is being made in the construction of the new chlorination works of the Merrifield mine. It is expected that it will be ready for operation in about 3 weeks. About 12 tons of fine rock taken out of the Johnson & Wheeler claim at Wood's ravine, is now being crushed at Keith's mill, and is yielding about \$20 per ton. The extra 5 stamps that are being put up at the mill of the Nevada City will be in running order by next Saturday.

Snow Point.—*Transcript*, July 14: Wand & Blackwell have 8 men at work on the main tunnel and drifts of their

new gravel discovery at Snow Point, and will increase the force as rapidly as room is made. The indications continue to be so favorable as they were last month.

ITEM.—Parties are prospecting for the lead on the opposite side of the ridge from Wand & Blackwell's claim.

DANIEL MIN.—The force of 80 white men at work at this mine was increased yesterday morning by putting on 24 Chinamen—the first Mongolians employed by the company. The new incline in Humburg creek, from which a bedrock tunnel is to be run to the vicinity of the hoisting works about 2,500 ft distant, has reached a depth of 75 ft.

GRAPHIC COX.—It is reported that within the past week the ledge in the new tunnel of this mine at Plinn valley increased in size from 19 to 36 inches, and is heavily charged with sulphurets. A force of 25 men is regularly employed in the mine.

PITTSBURG MIN.—*Transcript*, July 16: Work has been resumed in this mine, where nothing has been done for some time past. A contract has been let for sinking the incline, which is now down 850 ft, 150 ft further, so that the ledge can be developed at a depth of 1,000 ft. It is generally believed that this step will result satisfactorily.

The Pittsburgh has always proven a good mine when under proper management and with sufficient financial backing.

MILTON NOTES.—There is a great deal of prospecting being done in the neighborhood of Milton, on the line between Nevada and Sierra counties, since the snow disappeared this summer, and considerable excitement prevails. Work has been started on the Mastodon Con. Co.'s property, and the indications met with thus far are quite favorable.

Dr. Holdsworth and another party have just located a placer claim 1 mile in length on the Bald Mountain ledge. The Milton M. Co. sent down a \$3,000 brick from French Corral yesterday and it was shipped to the Bay.

LONG RIDGE M. Co.—*North San Juan Times*, July 17: This company is making arrangements for the construction of an iron pipe from Montezuma hill to their claims for the purpose of increasing their water power.

It is of the opinion that the expenditure will be compensated more than ten fold by the increase of bullion.

OAK VALLEY ITEM.—A silver ledge has been found at Oak valley, about 4 miles from Camptownville. Charles Biber and James McBride, in prospecting a quartz ledge for gold, came across some singular looking metal which they deemed worthless, and threw it aside. As they went down on the ledge they found larger quantities of the same, and finally concluded they would test it and see what it was. They did so, and found it to be silver. The ledge has been traced a distance of 4,000 ft, and the vein is 14 ft in width. Free silver is found all through the ledge, and the parties think they have struck a bonanza.

COLUMBIA HILL ITEM.—The Eureka Lako Co. have commenced sinking a shaft between their boarding house at Columbia hill and the old town of that name. They are determined to reach bedrock if possible, and if they find good paying ground, the company will run a tunnel to its Columbia Hill mines, commencing at the South Yuba river. The company is prospecting their mining ground at the old town to ascertain whether the ground will pay sufficiently to warrant the expense of a tunnel over 3 miles in extent.

KINGSLEY & HITCHCOCK.—*Transcript*, July 17: The incline on this mine in the north end district is now down 80 ft, the ledge at the bottom being 16 inches thick, and the walls clearly defined. The owners will continue extracting ore until they have realized enough gold to erect steam hoisting works, which they expect to be able to do this fall. To show the character of the ore, we will state that 15 tons of it, just as it came from the different parts of the ledge, averaged \$200 per ton.

BALD MOUNTAIN EXTENSION.—The tunnel of this company, near Forest City, is now in 2,200 ft, and the progress made is 150 ft a month. There are now only 1,400 more to run. Three shifts are being worked. The formation is still mountain lava. The Prest has ordered 2,000 ft of track from San Francisco.

BURZLOW MIN.—Owing to last week this mine, situated in the low end district, on the south side of the South Yuba river, has been producing very heavy sulphurets ore. When in 66 ft from the shaft the drift struck a 6-foot ledge. It is the same body of ore found in the shaft, but has increased in size to a remarkable extent.

ITEM.—Mr. Leahy has had a crushing made (the second) of 113 tons of dirt from the waste dump of the old Banner quartz mine in this district. He realized a little over \$8 a ton in free gold, besides 6% of sulphurets.

PLACER.

A RICH STRIKE.—*Herald*, July 17: Messrs. Nutting and Co. have just found the Cogsworth ledge near Clipper Gap. They have been prospecting on the ridge near the Auburn and Clipper Gap wagon road, and it is reported that they took out about \$1,000 in one day. Our informant says the find is scarcely second to the famous Pike Bell strike of a few years ago.

ITEM.—We learn that the mines at Last Chance are holding out well, and the season has been one of general prospecting and success. The Cogsworth ledge near Clipper Gap has been prospecting on the ridge near the Auburn and Clipper Gap wagon road, and it is reported that they took out about \$1,000 in one day. Our informant says the find is scarcely second to the famous Pike Bell strike of a few years ago.

LOWELL HILL NOTES.—*Dutch Flat Forum*, July 17: We are informed that the most extensive drift mining in Nevada county is on the ridge between Bear river and Steep hollow in close proximity to Lovell hill, where a great many thousand dollars have been expended in developing the immensely rich gold-bearing gravel leads.

EAST NEW YORK MIN.—The tunnel in this mine is in a fine state of about 2,000 ft, and they will now make an angle upward for the purpose of more fully determining what's there. The proprietors of this mine have taken out a large amount of gold since the mine has been opened.

WINE WEST.—The owners of this mine are working a force of 60 men. The tunnel is in about 900 ft, and they are working gravel that pays from \$2.50 to \$3 per car load. This mine is located a short distance from the Swamp Angel to the northwest.

MOROAN.—The tunnel in this mine, adjoining the Swamp Angel on the north, is in for a distance of about 1,100 ft, and plenty of pay gravel in sight. It is said to be the best arranged and equipped mine in that vicinity.

ITEMS.—We are informed that the Steep Hollow Tunnel Co. has struck, in the tunnel, at a distance of 180 ft, a lead of very rich blue gravel. This mine is between Lowell and Liberty hills. We understand a pretty fair strike has been made in the Franklin mine, just at the edge of town. There was \$15 taken out of two pans of dirt. They expect to find still better pay dirt soon.

PLUMAS.

ON THE LEAD.—*National*, July 16: There is not much doubt but that Loring & Leavitt have at last found the "pay streak" they have so long been looking for in their Elizabethtown claim, and that they will now reap the reward of years of patient toil. Mr. Loring showed us a nice lot of gold the other day, about \$100, which he says is taken from the mine. It is a fine, well-sorted, fashioned lead gold, some of the pieces weighing \$4 or \$5. The work since the pay channel has been found demonstrates that it is of considerable width, and there is reason to think that it will improve in richness as they drift up the canyon.

EMMAN'S MIN.—We learn from Eagle gulch that the owners of this mine are taking out very rich rock. The rock is taken from the mine, carefully assayed, and the best part of it crushed in a hand mortar, yielded about \$100 per day. The next grade is put into barrels and boxes, and will be worked in the arastra, and it is impossible to estimate what it will yield, but there is no doubt but that the figures will be astonishing.

GREENVILLE NOTES.—*Cor. National*, July 14: The Cherokee mine, owned by the Cherokee Mining Co. The yield in the old times was very large, but they were worked at a disadvantage, and no depth of any consequence was gained. Now, with the help of modern improvements in mining machinery, and with good management, the owners will open up one of the finest mines in the country. The Cherokee mines are connected with the far-famed Green Mountain.

ACACULAS.—This mine, in the same range of country, is one of the newly developed quartz locations. It was formerly known as the Savage and Wilson, and was worked some 12 years ago, but the company lost the pay streak and abandoned it. The present company has expended some \$2,000 in opening the mine, and last winter the work

proved successful. They have been taking out more bullion the last two months than the total of their expenditures, and there is still a large amount of pay ore in sight. The mine is situated within a half mile of the Kettis mill, where the rock can be hauled for 35 cents per ton, and a fine tract of timber adjoins the claim.

ITEMS.—The New York Co. start up their mill this week. The Southern Eureka is making a fine showing. The mines are all being worked this summer, and it is hoped that none will prove worthless.

SIERRA.

GOOD FLOW EXTENSION.—*Mountain Messenger*, July 17: A sample of the rock of the Good Hope Extension has been shown to us. It prospects about \$20 per ton. We believe this to be one of the best openings in the county.

THE 1001 MIN.—The owners of the 1001 mine are still pushing their work ahead, but have not yet reached the rim rock. The gravel is just as good as ever, and their prospects are very flattering.

PLUMASO MIN.—A run has been made at the Plumbago mine, at Minnesota, and the owners are satisfied with the clean-up.

TRINITY.

NEW RIVER NOTES.—*Cor. Journal*, July 17: At this time last year, ground sluicing was about over for want of water, but to-day hardly a is used, and as the snow is quite deep at this head of the creeks, we are assured of at least 6 weeks more running, or even 2 months.

DUTCH CO.—The Portuguese company is about to resume work on the ditch that they partially dug last summer. This is a ditch and mine some 3 miles long, and which, when completed, will carry water from the main river to what is known as Rattlesnake bar. This bar is some 25 acres in area and is just across the river from Big flat, and is said to prospect well throughout with a very high dump. They expect to have the water on it by next fall.

TUOLUMNE.

SPRING GULCH MIN.—*Independent*, July 17: We are pleased to state that the Spring Gulch mine is looking up in the shape of a bonanza. The owners concluded to sink 100 ft in their old shaft, and having attained a depth of 500 ft, they struck a vein of ribbon ore 2 ft at its bottom of the shaft, coming from the south and running north, which will go from \$40 to \$200 per ton.

NOTES.—Mr. Charles Waterman, one of the discoverers of the Olsen mine, has made another strike near Dunlap's, about 4 miles from Knight's Ferry, far exceeding in richness the first discovery.

YUBA.

EAGLE MIN.—*Marquette Appeal*, July 13: M. Higgins & Son, proprietors of the Eagle mine, at Indiana ranch, pocketed \$3,396 worth of gold crushed out by their 6-stamp quartz mill during the past 4 weeks. The mine has been paying excellently for 5 or 6 months past.

ITEM.—Supt. Jerome Deasy leaves this morning for the mines on the old Kessling claim, Rich gulch, having in his 3 large horse loads of material for the erection of hoisting machinery at the mines.

NEVADA.

WASHOE DISTRICT.

UNION CO.—*Gold Hill News*, July 21: Still cutting the drain in the main lateral drift, 2300 level. Winze No. 2 is down 50 ft below the 2400 level. South drift from winze No. 1 toward this winze is still in low-grade quartz containing places of greater value, but not milling ore as a whole. The northeast drift from Union shaft toward Sierra Nevada incline station, 2500 level, is averaging 7 ft per day. Total length to-day, 115 ft.

ORION.—The joint Mexican crosscut east on the 1000 level and to the Suro tunnel north lateral will be completed this week. The joint California raise from the 2300 level is advancing as rapidly as the extreme beat will allow. It is designed to connect with the joint winze from the 2000 level for ventilation.

CALIFORNIA.—The north drift on the 2300 level is making usual progress, no water material. It is designed to complete the connection on this level between the C. & C. and Union shafts.

CON. VIRGINIA.—The joint Beat & Belcher winze from the 2000 level, designed to connect with the 2300 level, has been commenced. No. 1 crosscut east on 2000 level is averaging 3 ft per day through good vein material carrying quartz in stringers.

SACRAMENTO.—The drift on the 1300 level has been swung round into a crosscut for the purpose of prospecting at a greater distance from the shaft the 11 ft of low-grade ore cut in the crosscut east after the clay wall was cut through. Bulkheading on the 2400 level against the water, on the 2200 and in this incline.

MEXICAN.—The drill run on the 2300 level has developed nothing of importance as yet, but some water has been encountered.

UNION SHAFT.—The 2500 pump is not yet running, but to-morrow connections will be made and it will be started as soon as these are completed. The work of raising the south compartment is now going on at 5 points, operations having been commenced on the 2000 level.

HALE & NORCROSS.—The endeavor to bulkhead the 2200 level against the Sacramento vein has been abandoned, owing to the loose character of the formation on that level south of the point where the stream flows into the drift.

SURO TUNNEL.—The headers of the north and south lateral branches are making excellent progress.

QUINN.—Sinking a winze in the casing of the ore body north of the main drift from the shaft, and encountering good ore. Still working to connect the old shaft with the 2000 level, and excavating for a station and tank on the 300 level.

SIERRA NEVADA.—The raise from the 2300 level to the bottom of the main shaft was commenced last Saturday, and is progressing well. The north drift on the 2400 level is to-day 1,050 ft in length, and is making 5 ft per day along the vein.

AURORA DISTRICT.

REAL DEL MONTE.—*Esmeralda Herald*, July 17: The tank and pump station on the 650 level has been completed and timbered up, and the tank put in place. During the week they have been engaged in putting in the pump, which will be in place by the end of the week. The connections are now being placed in position. When this is completed, sinking will be resumed.

CENTENNIAL.—There is no change in this mine as depth is attained. The ore is as rich at the bottom as at the top, and the width of the vein fully as great. Several tons are now on the dump.

GRAND TRUNK.—In the last week the crosscut has been advanced 21 ft. The face is now in quartz showing some mineral. It is thought next week will show what is the appearance of the ledge they are running for.

WEST ANTELOPE.—The Antelope is one of the old claims of the camp, from which so much rock was crushed in 1863-64. The West Antelope ledge appears to be a continuation of the Antelope, the rock being very similar. The ledge is from 3 to 4 ft in width, with well-defined walls.

THANKSGIVING.—The north drift is now in 21 ft, in good ore all the way. Several assays have been made from the ore taken from this drift, going as high as \$103.94 per ton. There is now about 150 tons on the dump ready for milling.

BRISTOL DISTRICT.

NOTES.—Pioche Record, July 10: The Bristol silver mining company is putting up the frame of their new mill and have already in place the battery, pans and settlers, and are rapidly pushing work ahead. The furnace of the Hillside mill and mining company started up Thursday with a large amount of ore in the dump and lead ore coming in rapidly. The Hillside 5th level, east, is daily improving, and more ore is being taken out than has been heretofore for some time past. Some fine lead ore is being shipped to the Hillside furnace from the Independence, Pioche.

CHERRY CREEK DISTRICT.

BROOKS MILL.—*Cor. White Pine News*, July 13: A portion of the machinery for Dr. Brooks' mill, at Silver canyon, is now on the ground, and everything is being pushed forward as rapidly as possible.

TEACUP MIN.—Profs. Newberry and Herr made a very thorough examination of the Teacup mine, taking samples from the face of every body of ore from this surface to the 770 level, spending 3 days at their labor and making a large number of assays.

COLUMBUS DISTRICT.

MOUNT DIABLO.—*True Vindicator*, July 17: The west drift on the 1st level has been advanced 11 ft this week. The east drift on the same level has also been advanced 10 ft. The crosscut north on the east drift has been extended 12 ft, and the crosscut south on the same level, 12 ft. The main shaft is down 343 ft, 10 ft having been made during the week.

LUCKY HILL.—The winze has reached a depth of 150 ft. The formation continues the same as noted before. The crosscut from the 110 level south is improving very fast. Some good ore is being taken out from this crosscut. The machinery for the hoisting works is expected in a short time.

CENTRAL JACKSON.—The lightning incline is still being sunk as rapidly as possible. The air in the crosscut from the lightning incline, southeast to the silver incline, is very bad, and work has been discontinued.

MOUNT ROSE DISTRICT.

STRIKE IN THE BULLION.—*Silver State*, July 17: We are informed by Deputy Sheriff Adams, of Paradise, that a very important strike has been made in the Bullion mine. Mr. Adams left Spring City on Tuesday, and he says he saw specimens of the ore which were covered with ruby and native silver. The foreman of the mine informed him that the ore body had been uncovered for several ft, and the ore was as rich, if not richer, than anything ever before found in the mine.

PIOCHE DISTRICT.

BULLIONVILLE MIN.—*Record*, July 10: Work will be resumed on the Bullionville mine, which is located about 15 miles southwest of town. Henry Raymond and a B. McGee have entered into an agreement with the owners of the above-named mine to do \$10,000 worth of work upon the same for 1/2 interest in the mine. The money was put up and work commences immediately.

INDEPENDENCE.—The boys engaged in taking out ore from the Independence mine, on Wednesday commenced hoisting it through the Newark shaft.

PARADISE DISTRICT.

CREDIT MOBILIER.—*Silver State*, July 17: We understand that operations are to be resumed on this mine shortly. This district, which is situated in the range of mountains between Paradise valley and the Humboldt river, must not be confounded with Mount Rose district, in which what are known as the Paradise mines are located. The Credit Mobilier is an old location, and a few years ago, when a shaft was sunk on the ledge, it produced some of the richest gold-bearing quartz ever found in this part of the country.

WHEEL COUNTY NOTES.—The Bullion, of the Paradise company, has, we are informed, purchased about the second-class ore at the Ohio mine, and are now making arrangements to have it hauled to the Sedan mill.

REBEL CREEK DISTRICT.

RICH ORE.—*Silver State*, July 17: We are informed that a body of ore has been struck in the Ohio mine, in Rebel Creek district, samples of which assay \$8,000 per ton.

EUREKA DISTRICT.

JACKSON.—*Sentinel*, July 11: The flow of water has been so great as to prevent operations in the main shaft for some time, and work has been confined to the 0th level.

DEADHORSE.—Martin Piantoni has struck an 18-inch vein of ore in the main shaft of this mine that will assay from \$100 to \$125. He expects to make a shipment to the Eureka Con. reduction works shortly. The main shaft of the mine is now down over 100 ft, and some 800 ft of drifts, etc., have been run.

EUREKA COX.—The mine continues to look well, and the 2 furnaces are running steadily, the ore-bins at the mine and at the reduction works being full. Prospecting is now chiefly confined to the 7th, 8th, 10th and 11th levels.

ARIZONA.

GLOSH DISTRICT.—*Silver Belt*, July 10: Messrs. Harrod, Hutchins & Yates, of Richmond basin, have presented Dr. Stalls cabinet specimen of Silver gulch ore which will assay \$8,000 per ton. These gentlemen are taking out very fine ore.

MACK MORRIS.—This mine is producing exceedingly rich ore. A short distance from the winze about 4 tons were taken out on Wednesday, which were supposed to contain \$3,600. This was only a part of the ore taken from the mine on that day, but was the most valuable per ton. Mr. Campbell informed us that 50 tons of rich ore were hauled from the mine to the mill on one day this week.

STONEWALL JACKSON.—Another most remarkable strike in the Stonewall Jackson is reported. If, as represented to us, it hegars description. Besides a 4-ft body of high-grade shipping ore, there is a 6-inch vertical streak of native silver on the footwall. We are not sufficiently advised to state at what depth the discovery was made, but are impressed with the belief that the ore discovered where the water came into the shaft (450 ft from the surface) with such volume as to temporarily force suspension of work.

COLORADO.

CLEAR CREEK COUNTY.—*Colorado Miner*, July 10: We have just made an examination of the Thunderbolt Dundee mine, and in all the various workings there is a fine quality about. There are 163 men employed. There are 4 levels in the upper workings in the A level, where a force of men are at work. The breast of this drift is now about under the Dundeeberg shaft. Two stops in the B level, some 60 ft above, are being worked. Assays from the ore found here have run as high as 14,000 ounces. The ore averages from 6 to 12 inches thick. The company has an assay office at the mine, so that after the ore has gone through the mill it is assayed, and its real value is known before it is shipped.

Origin and Classification of Ore Deposits—No. 2.

(By PROF. NEWBERRY, in the *School of Mines Quarterly* for March.)

Fissure Veins.

These veins occupy crevices which have been formed by subterranean forces and have been filled from a foreign source. They traverse indiscriminately all kinds of rock, and are without definite limits laterally or vertically. They have as characteristic features smooth, striated, sometimes polished walls (slickensides), clay-gouges or selvages on one or both sides, and a banded or ribboned structure throughout. The vein-stone is usually quartz, and the constituents include the ores of all the metals. The mode of formation of fissure veins is apparently this: In the regions where the earth's crust is broken up in the adjustment of the cold and hard exterior to the cooling and shrinking nucleus, cracks are formed, often miles in extent, along which the rocks suffer displacement, sliding on each other to form what are known as "faults." As the planes of these faults are more or less undulated, with displacement the bearing is upon the projecting bosses of each side. Between these, open fissures are left of greater or less dimensions. These reach down to a heated zone, and form the conduits through which thermal waters flow to the surface. Such waters coming in different localities from different depths, and leaching rocks of various composition under great pressure and high temperature, having great solvent power, become loaded with various mineral matters. As they rise to the surface, the pressure and temperature are reduced, and the materials held in solution are deposited to line and perhaps ultimately fill the channels through which they flow. This theory of the filling of mineral veins—that is, by precipitation from heated chemical solutions coming from below—is supported by such an array of facts that it must be accepted by all who will make a careful and unprejudiced study of the subject. It is true, however, that various other theories have been at one time or another put forth for the explanation of the phenomena. Among these, a few deserve a passing notice. They are:

1. *The theory of igneous ejection*, according to which the matter filling mineral veins has been erupted like that of trap dikes, and such veins as those of Lake Superior containing metallic copper have been suggested as affording good examples. But here we find metallic copper and silver associated, and each chemically pure; whereas, if they had ever been fused, they certainly would have formed an alloy. The copper is also found in crystals of calc-spar and other minerals, where it must have been deposited with the other constituents of the crystal, and that crystal formed from solution. Other opposing facts might be cited; but it will be sufficient to say that not one sound argument can be advanced in favor of this theory.

2. *Aqueous deposition from above*. This theory, first advanced by Werner, but since generally abandoned, supposes the contents of mineral veins to have been deposited from a solution which flowed into the fissures from above; but in that case the vein-matter should be horizontally stratified, limited in extent downward, and spread over the surface adjacent to the fissure; whereas no one has yet reached the limits in depth of the ore in a true fissure-vein, and the characteristic banded structure can only have resulted from successive depositions of long-continued flow of a hot solution. This theory has been recently advocated in this city, by Prof. Stewart of Nevada; but it is not only not sustained, but is really disproved by all the facts observed by the writer, in some years devoted to the study of our Western ore-deposits.

3. *Lateral secretion*. According to this theory, the material filling all mineral veins has leached into the cavity from the wall-rocks. While this is true of gash veins, it can have played but a very subordinate part in the deposition of ore in fissure veins. This is proved by the facts that different sets of fissures which cut the same formation frequently contain very different ores; and where the rocks of totally different character are, by faulting, brought to form opposite walls of a fissure, the ore may be symmetrically deposited in corresponding layers. It may also be said that the same fissure frequently traverses several formations, and yet its character may be essentially the same throughout.

4. *Sublimation*. The facility with which certain metals are volatilized, and the fact that various minerals have been deposited from vapor, have formed the basis of this theory; yet it is difficult to see how any one can ascribe more than a local and insignificant effect to this cause. It is true that the action of water, as steam, is much the same as when fluid and highly heated, in the solution and transport of minerals; and the deposit of mercury, sulphide of iron and even gold, from the mingled steam and water of the California geysers proves this. So we may concede that steam has been an agent in the chemical solution and precipitation of ores; but this is a very different thing from the sublimation of the metals represented by these ores, and all knowledge and analogy indicate that the silica which forms so large a part of vein-stones, and is so often seen in combs of interlocking crystals, has been deposited from an aqueous solution. But argument is really wasted in a discussion of the filling of fissure veins, since we have examples that seem to settle the question in favor of chemical precipi-

tation from ascending hot water and steam. In the Steamboat springs of western Nevada, for example, we in fact catch mineral veins in the process of formation. These springs issue from extensive fissures which have been or are filling with siliceous vein-stone that carries, according to M. Laur, oxide of iron, oxide of manganese, sulphide of iron, sulphide of copper and metallic gold, and exhibits the banded structure so frequently observed in mineral veins.

In regard to the precise chemical reactions which take place in the disposition of ores in veins, there is much yet to be learned, and this constitutes an interesting subject for original investigation, which I earnestly commend to those who are so situated that they can pursue it.

It may be noticed, however, that the thermal springs that are now forming deposits like those in fissure veins, contain alkaline carbonates and sulphides, and we have every reason to believe that highly carbonate alkaline waters containing sulphureted hydrogen under varying conditions of temperature and pressure are capable of taking into solution and depositing all the metals and minerals with which we meet in mineral veins.

To these necessarily brief notes on the filling of mineral veins should be added some interesting examples of the mechanical filling of fissures which have been recently brought to light in Western mining. These are furnished by the remarkable deposits of gold and silver ore in the Bassick and Bull-Domingo, near Rosita, Colorado, and the Carbonate mine at Frisco, Utah. All these are apparently true fissure veins, filled to as great a depth as they have yet been penetrated, by well-rounded pebbles and boulders which have fallen or been washed in from above. The porous mass thus formed has been subsequently saturated with a hot ascending mineral solution, which has cemented the pebbles and boulders together into a conglomerate ore. In the Bassick, this ore consists of rich telluride of silver and gold, free gold, and the argentiferous sulphides of lead, zinc, copper and iron. In the Bull-Domingo and Carbonate mines, the cementing matter is argentiferous galena. That the pebbles and boulders have come from above, is distinctly shown by the variety in their composition and the organic matters associated with them. In the Bull-Domingo and the Bassick, the pebbles consist of various kinds of igneous rock, mingled with which in the latter are masses of silicified wood and charcoal; while in the Carbonate mine, the pebbles are mainly trachyte; but with these are others of limestone and quartzite.

Fossils and other foreign bodies have before this been found in mineral veins, and Von Cotta mentions the occurrence of quartz pebbles, extending to the depth of 155 fathoms in the Gruner Lode at Schemnitz, Saxony; but no conglomerate veins like those mentioned above are known to exist elsewhere, and they constitute another of the many new forms of ore-deposit which the exploration of the rich and varied mineral resources of the United States has brought to light. To enumerate and classify these, has been the chief object of this article.

In regard to the ultimate source of the metallic matters which give value to our ore-deposits, but little can be said with certainty. The oldest rocks of which we have any knowledge, the Laurentian, contain gold and copper, which are indigenous, hence as old as the rocks that contain them, and have been simply concentrated and made conspicuous in the process of their metamorphism. These rocks are all sediments, and the ruins of pre-existing continents. By their erosion, they have in turn furnished gold, copper, iron, etc., to later sediments by mechanical dispersion and chemical solution. We now find gold everywhere in the drift from the Canadian Highlands, and we have every reason to believe that all the sedimentary strata more recent than the Laurentian have acquired a slight impregnation of several metals from them in addition to what they have obtained from other sources, and we may conclude that the distribution of many of the metals is almost universal. Sea-water has been proved to contain gold, silver, copper, lead, zinc, cobalt, nickel, iron, manganese and arsenic; and there is little doubt that all the other metals would be found there if the search were sufficiently thorough. Hence, sedimentary rocks of every age must have received from the ocean in which they were deposited some portion of all the metals, and for the formation of metalliferous deposits some method of concentrating these would alone be required. A pretty theory to explain such concentration through the agency of marine plants and animals has been suggested by some German mineralogists, and amplified by Profs. Pumpelly and T. S. Hunt. Plants have been credited with the most active agency in this concentration; but evidence is still wanting that either plants or animals have played any important part in the formation of our mineral deposits. The remains of sea-weeds are found in the greatest abundance in a number of Paleozoic rocks, and it is almost certain that the carbonaceous ingredient in our great beds of bituminous shale has been derived from this source; yet we find there no unusual concentration of metallic matter, and none of the precious metals has ever been detected in them.

The metallic solutions which have formed our ore-deposits have been ascribed to two sources. One theory supposes that they have drained highly metalliferous zones deep in the interior of the earth; the other, that they have leached diffused metals from rocks of different kinds comparatively near the surface. The latter

view is the one that commends itself to the judgment of the writer. However probable such a thing might seem, no evidence of the existence of distinct metallic or metalliferous zones in the interior of the earth has been gathered. On the contrary, volcanic emissions, which may be supposed to draw from a lower level than water could reach, are not specially rich in metallic matters, and the thermal waters which have by their deposit filled our mineral veins must have derived their metallic salts from a zone not many thousand ft. from the surface. The mineral springs, which are now doing a similar work, are but part of a round of circulation of surface-water, which, falling from the clouds, penetrates the earth to a point where the temperature is such as to drive it back in steam. This, with fluid water under pressure and highly heated, possessing great solvent power, may be forced through vast beds of rock, and these be effectually leached by the process. Should such rocks contain the minutest imaginary quantity of the metals, these must inevitably be taken into solution, and thus flow toward or to the surface, to be deposited when, by diminished temperature and pressure, the solvent power of the menstruum is diminished. It is evident from these facts that we cannot trace the history of the metals back beyond the Laurentian age. And since we find them diffused in greater or less quantity through the sedimentary rocks of all ages, and also find processes in action which are removing and redepositing them in the form of the ore deposits we mine, it is not necessary to look farther than this for a sufficient theory of their formation.

Baggage Checks in Court.

Passengers cannot complain if checks for baggage are not given; nor is one company bound to give them because others do. Upon the other hand, the refusal to give checks does not impair the passenger's rights; he is entitled to have his property safely carried and re-delivered to him at the end of the trip, check or no check. In Missouri a traveler came to a depot in St. Louis bringing a trunk and a roll of carpeting, and asked for checks for both. The baggage master gave him one for the trunk, but would not give any for the carpeting, for, he said, he would strap it on the trunk, and one check would do for both. But the carpeting was lost on the journey, while the trunk was safely delivered. In the lawsuit the company said that the baggage master was forbidden to give checks for anything but proper baggage; that passengers were not entitled to carry carpeting in rolls; and as this piece was not checked, there was no liability. But the court said that if the baggage master thought that the parcel was not proper baggage, he should have refused to take it. By accepting it for baggage, he rendered the company liable, and his declining to give a check did not make the slightest difference in the legal responsibility. In Connecticut a traveler brought his trunk to the station in the forenoon and asked to have it checked for the 3 P. M. train to Bridgeport. The baggage master said that baggage could not be checked for that train until a quarter before three. The traveler then left the trunk in the baggage room. At a quarter before three he returned, obtained a check, and in due time traveled to Bridgeport. On arriving there he found that money and clothing had been stolen from the trunk; but whether during the trip or while the trunk was lying unchecked in the baggage room no one knew. And the court said that this made no difference. If the baggage master received the trunk as baggage to be carried for a passenger, the company was liable for it from that moment, check or no check. The check is in the nature of a receipt, which may be given at any time; it is not the contract, but only evidence of the delivery and identity of the baggage. What fixes the liability of the company is the passenger's delivering it and the baggage master's accepting it for transportation; and the liability begins at the moment of the delivery and acceptance.—*Railroad Gazette*.

GRAVEL MINES AT DAYTON, NEV.—It now seems, says the *Gold Hill News* of July 15th, that the Dayton gravel mining company is about to be paid for the time, trouble and expense of locating their claim and opening it up. They have sunk 20 ft. to bedrock and run a tunnel 180 ft., which gives about two ft. of good pay dirt on top and 10 inches on the bedrock, which is rich. The bedrock is soft lava, just the stuff to catch and save fine gold. This pay dirt must be raised the 20 ft. and washed. A bucketful (eight pans) recently gave \$1.50. Washing has to be done with the water of Gold Canyon, which is at times unfit for use; still it will do something. The mine is 34½ ft. above the Carson, and if the company was wealthy enough to get the water company to run a flume down there and give them clean water with a fair head, so that they could commence and sluice back from the river to their claim, which consists of 160 acres, it seems as though that would be the way to get their gold. Doubtless the sluicing of the channel back to the claim would pay the outlay. Even with present facilities it looks as though there was coin for the company in their undertaking. Two men just above the claim of this company washed out \$270 in four weeks without any facilities whatever; and now that the company have at command so much good dirt near the bedrock, they ought to get their money back, and more too. Their gold is worth \$15.30 per ounce.

The Course of Empire.

"Westward the course of empire takes its way" quotes the *Chicago Journal of Commerce*. Since the census of 1870 the Western States and Territories have shown a wonderful increase in their populations. It is yet too soon to obtain results, but as a striking instance of this increase, we may cite Nebraska. The returns so far received from that State show that its population has increased from 128,000 to 500,000. Under the new reapportionment Nebraska will secure about four additional Congressmen. Notwithstanding the large increase in the State—nearly 400%—the population of Omaha has increased but 16,000 in the past decade. As Senator Paddock says, "this illustrates the desire of the European immigrant to possess a farm rather than a city." Unquestionably when the returns are in from Kansas, Wyoming Territory, Dakota and Minnesota, we shall find that their increase has been little else than remarkable. Nebraska has rightly assumed the place of one of the most prosperous States of the Union within the past 15 years. Her progress has been a marvel of energy and success. When the Colfax party went up the Platte valley in a stage coach in 1865, there were a few scattered settlements and cities on paper along the Missouri river, and Fort Kearney, with a few houses surrounding it, with stage stations at regular intervals, were all the signs of life found to the west line of the State, and, in fact, all the way to Denver. For 200 miles or more there were new-made graves to mark the slaughter of white men and women and children by the murderous redskins of the year before. The Union Pacific railway has changed all this, and now farms and hamlets and thriving towns dot the valley of the Platte all the way to the mountains. And it should be known that this great valley, prosperous and growing rapidly as it is, is by no means the best part of the State. The country on either side, beyond the bluffs that bound it, is richer by far than what the tourist sees as he dashes by on the cars in the Platte valley. It is a rich, rolling prairie, well watered, and is still rapidly settling by an energetic, thrifty population. The valleys of the Niobrara, the Elkhorn and the Loup Fork drain the northern half of the State. The Platte sweeps nearly through its center from east to west, while the Republican and other streams drain the southern sections. The result of the census just taken goes to show how ignorant the old geographers were when they marked a large portion of Nebraska and Kansas, which we used to see in the atlas of our school-boy days, as the "Great American Desert."

THE GOOD WORK OF A FRENCHMAN.—An agreeable duty of the French Academy each year is to award the Monthyon prizes, says the *New York Mail*, of which one is given to the author of the work most conducive to the promotion of public morals. The latter prize was bestowed last year on Hector Malot for a novel, which has been translated under the title "No Relations," and published by Messrs. J. B. Lippincott & Co., Philadelphia, in an inexpensive though well-printed form. It would be wise for those story-tellers who desire their works to teach a good moral lesson to study the art of Malot. Without preaching, without sermonizing, without enunciating moral axioms, by the acts of his personages and the development of his plots alone, the charming art of the author renders virtue attractive. He depicts with entire probability a child sold by the husband of his foster mother to a strolling fiddler, and yet growing up free from vice, and with a loving, grateful and good nature. The child is supposed to be a foundling, but turns out to have been stolen from a rich mother to whom he is restored. From the account of the vagabond life of the lad we rise with a better opinion of human nature, and deep admiration of the healthy imagination of the author, who, by his simple, sweet and unaffected narrative, has cast the glow of romance over people in very humble circumstances, and given a succession of descriptions remarkable for clearness and delicacy.

GOLD MINING IN AUSTRALIA.—We have received the official report on the mineral statistics of Victoria for the last year. The gradual development of the newly discovered lodes at Ballarat and the improved yield from lode mines at Maldon and other places, together with the assistance rendered to prospecting by the government diamond drills, appear to have a beneficial effect upon mining enterprise, as the report shows a slight increase. The quantity of quartz crushed during the past year was about 20,000 tons less than in 1873, but the yield of gold nearly 1,000 ozs. in excess. The average yield of crushing stuff was 1 cwt. 14.96 grs., being a less average than that of 1878. The decline in the mining population has been arrested and there is an increase of alluvial miners to the number of 265, and 652 quartz miners, on the preceding year. The Chinese are under 10,000, and show a decrease of 523 on the year. The average earnings is £76, or 30s per week. In the way of deep sinking, it is mentioned that one of the shafts at Stawell is 2,273 ft. in depth.—*Thames (N. Z.) Advertiser*.

RAWHIDE FOR JOURNAL BOXES.—Rawhide is said to make good journal boxes for machinery. A practical machinist says: "I have run a piece of machinery in rawhide boxes for 14 years without oil; it is good yet, and runs at 4,500 revolutions per minute. I put it in while soft and let it remain until dry."

THE ENGINEER.

Fast Railroad Time.

Experiments to Test the Speed that May be Reached by Locomotives.

A short time ago the New York Times printed a letter from a correspondent who undertook to correct a statement that a train which it is proposed to run regularly between Jersey City and Philadelphia—90 miles in 90 minutes—would be among the fastest in this world. His examples of fast trains were not so striking as they might have been made, however. Knight's "Mechanical Dictionary" records that Stephenson's Rocket traveled at the rate of 60 miles an hour over 50 years ago, when the art of building locomotives was in early infancy. The same authority gives 81 miles in 81 minutes, made by a special official train on the New York Central railroad, as the fastest time ever made in the United States. Scarcely inferior is the record of 72 miles in 73 minutes, made by a train between Lima and Dayton, including two stops. The best English record is 13 miles in 10 minutes, or at the rate of 78 miles an hour and one mile in 46 seconds. The special train which carried to Queen Victoria the decision of this Government in the Trent difficulty, in 1862, ran 31 miles in 144 minutes, or at the rate of 54½ miles per hour. These are exceptional cases, however, and if there is any train in the world which proposes a regular schedule time of 9 miles in 90 minutes, with no deductions for any cause—which is a very difficult thing from the occasional rate of a mile a minute—its existence is not generally known.

Probably the fastest train in England is that between London and Swindon, on the Great Western railroad, which travels at the rate of 53½ miles per hour. The northwestern road runs a train from London to Rugby at the rate of 4½ miles per hour, and the Great Northern Co. one from London to Peterborough at the rate of 50 miles in 60 minutes. The London-Heyhead, or "Wild Irishman" train runs only at the rate of 43 miles. Probably the fastest French train is the one which runs from Paris to Larseilles at the rate of 40 miles an hour, and on the Berlin and Hamburg road a train covers the 57½ miles between Spandan and Stieritz at the rate of 12 miles per hour. American need not be ashamed to add to the record the Pennsylvania railroad train between Jersey City and Germantown junction at the rate of 49 miles per hour, and the proposed train, taking the average of the whole distance is, as we said, the fastest regular train run.

The pattern of engine by which it is proposed to attain this result, though common in England, is unusual, though by no means unknown here, and is a curious instance of reversion to an original type. Our engines are designed rather for power than speed; and as an engine's dragging power depends largely upon the adhesion of its driving wheels, our engines are generally heavily built, and have at least four drivers, in order the better to distribute the weight. An extreme example is an engine built in 1878, with eight driving wheels. It weighed 118,000 lbs., and we have never seen any correction of the statement then made that it was the largest and most powerful engine ever made in the United States. In engines of this type, the driver have to be coupled together by the "parallel-rods," which are subjected to an enormous straining strain, when the engine is put to its speed, and which have been known to break in disastrous results. And even where this risk is taken, it is very hard to make small wheels evolve fast enough to give great speed.

The remedy indicated is to increase the size of the drivers, and to get rid of the connecting-rod by reducing the number of drivers. Accordingly we find the new engine to be in this respect, very much like Stephenson's "Rocket." It has only two driving wheels—one on each side, and not both on the same side, as the Railroad Gazette seems to have misunderstood the Times say—and each is connected directly with a driver. In order to redeem its schedule promises, this engine will have to travel sometimes at least 70 miles an hour, as it is necessary to slacken speed in rounding curves and pang through cities. The drivers are to be 6½ ft. diameter, which is a foot larger than is usual in this country, although in England, as our correspondent pointed out, 7½-ft. drivers are frequent, and, we believe, one engine has 10-ft. drivers.

EXTINGUISHING FIRES WITH STEAM.—The technic journals are again mooted the subject of the extinguishment of fires by means of steam, which appears to attract periodical attention. There can be no question that under certain circumstances, the application of steam for this purpose named will be vastly more useful and active than that of any other agent. The circumstances may be briefly described to be where a building, or portion of a building, is on fire where the fire has not burned out to their. Under these circumstances steam may render invaluable service, since, in most cases, this character, the fire can be speedily extinguished by its use with but a fraction of the loss to merchandise that invariably attends the use of water.

USEFUL INFORMATION.

ALUM IN BREAD.—Ostensibly, baking powders, for the most part, have for a basis cream of tartar and carbonate of soda; but cream of tartar itself is notoriously subject to adulteration, inasmuch that it is kept by wholesale dealers in distinctive grades, the lowest being grocers'—commonly adulterated with an earth which contains alum—the kind retailed to mix with an equally impure carbonate of soda as extemporized baking powder for home-made bread. To discover whether bread is adulterated with alum, soak a portion in water, and add to the water, in which the bread has been soaked, a solution of chlorides of lime, a little at a time, carefully stirring; if alum is present the mixture will be pervaded with milkiness, otherwise this liquid will remain limpid. To detect alum in flour is more difficult. The only safe course for housekeepers is to use flour and baking powders of known brands; to eschew all extemporaneous baking powders especially; and use such only as are known to be chemically pure and free from all injurious substances. And in this connection, without any reflection on such as have not been brought to our notice, we feel fully warranted in recommending this brand we have long used in our own household—the "Royal Baking Powder"—which we have frequently examined, and always without finding any impurity whatever.

ELECTRICAL PAVEMENTS FOR CITY LOCOMOTION.—The latest suggestion for the use of electricity as a motive power is to have the streets of cities paved with iron, either in blocks or so arranged that the pavement will form continuous electrical conductors, divided into suitable sections, each section to be charged with electricity by a stationary steam engine and dynamo machine of proper size. On the electrical pavements thus provided, wagons, carriages, fire engines, omnibuses and other vehicles, each provided with an electrical driving wheel, and taking electricity through the wheel from the pavement, may be run, in any desired direction, with more ease and certainty than by the present system of horse locomotion, although that system would not necessarily be interfered with, as those who preferred to use horses could of course do so. Iron pavements could doubtless be made that would be quite as serviceable as the present stone blocks. The subject presents a fine opportunity for students of electricity to exercise their head gear.—*Scientific American*.

CURIOUS FACT.—If a small bit of camphor is laid upon water, it begins turning and moving about with great rapidity. If a few grains of lycopodium or other light powder have been previously scattered on the water, they are drawn toward the camphor by eddies in an inverse direction. These phenomena were observed in 1748 by Romieu. Cassamajor has, says *Les Mondes*, resumed the study of the question and adopted the views of Romieu. He instances the following crucial experiment: At the same time that the bits of camphor are thrown upon the water, insert a glass rod which has been rubbed with flannel; the motion immediately stops. If the electricity is removed from the rod by rubbing it with tinfoil, it loses its power of checking the eddies.

REMOVAL OF STRONG ODORS FROM THE HANDS. Ground mustard, mixed with a little water, is an excellent agent for cleansing the hands after handling odorous substances, such as cod-liver oil, musk, valerianic acid and its salts. Scale pans and vessels may also be readily freed from odor by the same method. A. Huber states that all oily seeds, when powdered, will answer this purpose. In the case of almonds and mustard, the development of ethereal oil, under the influence of water, may perhaps be an additional help to destroy foreign odors. The author mentions that the smell of carboric acid may be removed by rubbing the hands with damp flax-seed meal, and that cod-liver oil bottles may be cleansed with a little of the same, or olive oil.—*Druggists' Circular*.

TO REMOVE INK FROM DRESS GOODS.—Oxalic acid is considered one of the best agents for this purpose. Dissolve 10 cents' worth in a pint of soft water; dip the stained spots in it quickly, and then into clear water, and rub well; repeat the process until the stains are removed. If the goods remain in the acid, the texture will be destroyed. The skin of the hands is unpleasantly affected if brought into frequent contact with a strong solution; care should be taken to dip only the spots into this liquid. If the color of the dress is affected, mix with warm water and wet with a dilute solution of ammonia, which will restore the original color. Ink stains on table covers can be removed in the same way.

TO "dry" linseed oil without boiling it, add to old oil about two per cent. of borate of manganese, and heat in water bath to at most 225° Fahr., stirring well.

TO REMOVE ink stains from linen, with a clean rag or sponge rub the soiled spot with lemon juice in which has been dissolved a small quantity of salt.

OSTRICH feathers may be bleached by exposing them to the light of the sun in an atmosphere saturated with the vapors of benzine, turpentine or petroleum.

ARTIFICIAL WINES.—The ravages of the phylloxera have greatly increased the demand for "artificial wines" and brandies, or those made from raisins. E. Martin undertakes the defence of these products, and says that chemical analysis can show no difference between them and those which are made from fresh grapes. He states, however, that it is better to add an equal portion of fresh grapes, so as to quicken the fermentation which has been rendered sluggish by drying. When this is done, he defies the most skillful connoisseur to detect two specimens of artificial wines among eight others of natural wines.—*Chron. Indust.*

TO TAKE BRUISES out of furniture, wet the part with warm water; double a piece of brown paper five or six times, soak it in the warm water, and lay it on the place; apply on that a warm, but not hot, flat-iron, till the moisture is evaporated. If the bruise be not gone, repeat the process. After two or three applications, the dent or bruise will be raised to the surface. If the bruise be small, merely soak it with warm water, and hold a red-hot iron near the surface, keeping the surface continually wet—the bruise will soon disappear.

A NEW BREED OF WHALES.—A whaling captain, lately returned from the arctic seas, declares that a new breed of whales have made their appearance in those waters. They are supposed to have emigrated from the open sea at the Poles. The skipper describes them as very much larger than the old whales, and very gentle and confiding. In former years, when a whale was harpooned the rest of the herd threw up their flukes and made off. The new breed do not seem to mind in the least the capture of one of their number.—*Ex.*

TEA TWO HUNDRED YEARS AGO.—The London Gazette of December 16, 1680, has the following: "These are to give notice to persons of quality that a small parcel of most excellent tea is by accident fallen into the hands of a private person to be sold; but, that none may be disappointed, the lowest price is 30 shillings a pound, and not any to be sold under a pound weight, for which they are desired to bring a convenient box. Inquire at Mr. Thomas Eagle's, at the King's Head, in St James' Market."

ASH OR HICKORY FOR TOOL HANDLES.—A correspondent of the *Wheelwright and Blacksmith* wishes to know the relative value of "maiden ash" and hickory for tool handles, and also what "maiden ash" is. That journal, in reply, says that "maiden ash" is an ash sapling that has never been lopped; it is no better than hickory.

ANY fibrous material can be stuck to metal, whether iron or other metal, by an amalgam composed of good glue dissolved in hot vinegar with one-third of its volume of white pine pitch, also hot. This composition, it is said, will give a sure and certain result.

M. DRONER has patented in Germany a process for rendering bronze as malleable as copper. About one per cent. of mercury is added to the tin in a warm state, and this is then mixed with the melted copper.

DILUTE acetic acid has been successfully used by Dr. Ambuehl in extracting lead from alloys of tin and lead. He found Banca tin to be quite free from lead and English bar tin to contain only a slight trace.

GOOD HEALTH.

What to Do in Cases of Diphtheria.

In the first place, as diphtheria is a contagious disease, and under certain circumstances not entirely known, very highly so, it is important that all practical means should be taken to separate the sick from the well. As it is also infectious, woolen clothes, carpets, curtains, hangings, etc., should be avoided in the sick room, and only such material used as can be readily washed.

All cloths, when removed from the patient, should be at once placed in hot water. Pocket-handkerchiefs should be laid aside, and in their stead soft pieces of linen or cotton cloth should be used, and at once burned.

Disinfectants should always be placed in the vessels containing the expectoration, and may be used somewhat freely in the sick room; those being especially useful which destroy bad odors without causing others (nitrate of lead, chloride of zinc, etc.) In schools there should be especial supervision, as the disease is often so mild in its early stages as not to attract common attention; and no child should be allowed to attend school from an infected house, until allowed to do so by a competent physician. In the case of young children, all reasonable care should be taken to prevent undue exposure to the cold.

Pure water for drinking should be used, avoiding contaminated sources of supply; ventilation should be insisted on, and the local drainage must be carefully attended to. Privies and cesspools, where they exist, should be frequently emptied and disinfected; slop water should not be allowed to soak into the surface of the ground near dwelling-houses, and the cellars should be kept dry and sweet.

In all cases of diphtheria fully as great care should be taken in disinfecting the sick room, after use, as in scarlet fever. After a death from diphtheria, the clothing disused should be

burned or exposed to nearly or quite a heat of boiling water. The body should be placed as early as practicable in the coffin, with disinfectants, and the coffin should be tightly closed. Children, at least, and better adults also in most cases, should not attend a funeral from a house in which a death from diphtheria has occurred. But, with suitable precautions, it is not necessary that the funeral should be private, provided the corpse be not in any way exposed.

Although it is not at present possible to remove at once all sources of epidemic disease, yet the frequent visitation of such diseases, and especially its continued prevalences, may be taken as sufficient evidence of insanitary surroundings, and of sources of sickness to a certain extent preventable.

It should be distinctly understood that no amount of artificial "disinfection" can ever take the place of pure air, good water and proper drainage, which cannot be gained without prompt and efficient removal of all filth, whether from slaughter houses, etc., public buildings, crowded tenements or private residences.—*From the Circular of the Massachusetts State Board of Health.*

The Use of Pain.

The power which rules the universe, this great tender power, uses pain as a signal of danger. Just, generous, beautiful Nature never strikes a foul blow; never attacks us behind our backs; never digs pitfalls, or lays ambuscades; never wears a smile upon her face when there is vengeance in her heart. Patiently she teaches us her laws; plainly she writes her warnings; tenderly she graduates their force. Long before the fierce red danger-light of pain is flashed, she pleads with us—as though for her own sake, not ours—to be merciful to ourselves, and to each other. She makes the overworked brain to wander from the subject of its labors. She turns the over-indulged body against the delights of yesterday. These are her caution signals, "Go slow." She stands in the filthy courts and alleys that we pass daily, and beckons us to enter and realize with our senses what we allow to exist in the midst of the culture of which we brag. And what do we do for ourselves? We ply whip and spur on the jaded brain as though it were a jibing horse—force it back into the road which leads to madness and go on full gallop. We drug the rebellious body with stimulants; we hide the signal and think we have escaped the danger, and are very festive before night. We turn aside, as the Pharisee did of old, and pass on the other side with our bandkerchief to our nose. At last, having broken Nature's laws and disregarded her warnings, forth she comes—drums beating, colors flying—right in front to punish us. Then we go down on our knees and whimper about it having pleased God Almighty to send this affliction upon us, and pray him to work a miracle in order to reverse the natural consequences of our disobedience, or save us from the trouble of doing our duty. In other words, we put our finger in the fire and beg that it may not hurt.—*Ex.*

SKIN GRAFTING FROM THE DEAD.—Dr. J. H. Girdner, house surgeon at Bellevue Hospital, has obtained some remarkable and valuable results in skin grafting during the past year. One patient who required such treatment refused to furnish grafts from his own arms or body, owing to the pain involved; and, unwilling to ask another to subject himself to a pain which the person to be benefited was unwilling to submit to, Dr. Girdner tried the experiment of taking skin grafts from a corpse. The doctor says: "I cut a piece of skin from a patient who died in the wards a few hours before, first taking care to inquire whether the cause of death was due to a poisonous disease or not. I then cut the cuticle into small pieces, which I laid on the granulated surface of the ulcers, and hand-aged the leg up very firmly. In three days the graft began to show signs of life, a perfect union having taken place, and in a week a splendid skin, smooth and elastic, had grown over the ulcerated part, making a complete cure and leaving no scar behind. Since that time I have treated upward of 50 cases with invariably success. I have grafted the skin of an Irishman on a negro, and I have grafted the skin of a negro on an Irishman with ease. In both cases the skin lost its original color and changed its hue to suit the wearer."

THE EFFECT OF ELECTRIC LIGHT UPON THE EYES.—A Russian correspondent of the Paris *Temps* speaks as follows as regards this matter: "Kronstadt was the first city in Russia where the electric light was introduced into public and private buildings, and it has also been the first to discover its inconveniences. Diseases of the eyes having become more frequent, the attention of the government and of oculists has been turned towards the means of preventing these sad effects. The officer commanding the Black sea fleet has reported several cases of the sudden loss of sight caused by the dazzling of these lights used on board, and having an illuminating power of 14,000 candles. Dr. Lohinski, a specialist and an authority in these matters, has investigated this question, and finds that the use of blue glasses is the best protection against the Jablochhoff light. Next to this comes the gray glasses, and then the violet. Clear yellow tints, and also red, should be carefully avoided, for instead of decreasing the ill effects of the electric light upon the eye, these colors render it more injurious."

THE ENGINEER.—Fast Railroad Time; Extinguishing Fires with Steam, 55.

USEFUL INFORMATION.—Alum in Bread; Electrical Pavements for City Locomotives; Curious Fact; Removal of Strong Odor from the Hands; To Remove Ink from Dress Goods, 55.

GOOD HEALTH.—What to Do in Cases of Diphtheria; The Use of Pain; Skin Grafting from the Dead; The Effect of Electric Light Upon the Eyes, 55.

NEWS IN BRIEF on page 60 and other pages.

Business Announcements.

Metallurgical Works—Mathey, Kustel & Riette, N. Y.

The Week.

Business continues dull in the city, and from all appearances is likely to remain so for several weeks. It is the seasonable condition. After a brief time the general vacation will be over, and men will resume their enterprises with renewed vigor, spirit and intelligence. The condition of business in the State is satisfactory, and both farmer and miner are likely to increase their respective products greatly beyond the yield of last year. The outlook for the vineyardists is especially cheering.

The interest in the condition of the Comstock increases. Operations in the great mines at the north end are followed with intelligent anxiety. The pump on the 2500 of the Union Con. is said to be the key to the north end; for it will admit of the draining of the Sierra Nevada incline and permit the connection of the northwest drift on the 2500 of the Union with the station of the incline; in fine, it will "loosen the bands which bind Sierra Nevada and prevent cross-cutting on the 2400 north, and will permit the opening of the 2500 of Union." Savage is erecting bulkheads against the inflow of water; and towards the south they are ventilating the mines on a magnificent scale.

The Chamber of Commerce has adopted resolutions calling the attention of our Congressional delegation to the importance of continuing the geographical and topographical surveys of the States and Territories west of the 100th meridian, and urging them to vote for liberal appropriations for prosecuting the same. And also that the members be invited to work actively to secure an appropriation for a marine survey of the entire coast, and the early issuance of charts and maps of the same. This last resolution has special reference to the coast of Alaska.

Since our last issue the reports from the outside mines—notably those of Bodie and Columbus districts—have been meager, but on the whole, quite encouraging.

A Distinguished Engineer.

There arrived in this State a few days since a citizen of shining mark—Mr. James B. Eads, one of the most distinguished engineers of the country. He has already achieved a reputation as wide as the world as the most successful manager of great and difficult engineering projects. As an engineer, Mr. Eads has long since become conspicuous for the seeming audacity of his projects, no less than for the remarkable constructive talent which has enabled him to carry them to successful and brilliant conclusion. There is no doubt that the skillful engineering management of the remarkable bridge at St. Louis was due chiefly to Mr. Eads. For in a paper recently read before the British Institute of Civil Engineers, on the "Recent Progress in Engineering," the first place is assigned to that great work as the engineering feat accomplished during the last 50 years.

In tracing briefly the brilliant career of Mr. Eads we summarize the very intelligent account of his achievements from the *Sacramento Record-Union*. Mr. Eads became familiar with the Ohio and the Mississippi rivers when in his early years he was engaged in running steamboats on their waters. It is said that he was first a steamboat clerk, a pilot and then a master. Subsequently he became an owner of boats, a manager of works for a large heating and contracting company, and while thus engaged in superintending the raising of sunken vessels, the construction of wharves and other river works, he was afforded special opportunities for studying the laws governing the science of hydraulics as applicable to the improvement of rivers, and daily presented to view by the flow of the Father of Waters. During the war of the rebellion he became prominent as a contractor and builder of ironclad vessels, and showed his ability in successfully conducting various other engineering enterprises.

In his second great engineering work—that of improving the channel at the mouth of the Mississippi—Mr. Eads achieved high credit, mainly for having persistently advocated the jetty system as the most efficient method of opening a deep navigable mouth to the river. He did this in the face of the most strenuous opposition on the part of other engineers, who declared that the effect of jetties in obtaining and preserving a deep-water channel in this instance would not be favorable, and that the proper method was to construct a canal, with locks, as an artificial entrance to the great river. Mr. Eads not only indicated the true means of improving the outlet of the Mississippi, but with remarkable energy and intelligence he secured capital to carry out his plan and procured the passage of a bill through Congress, pledging the Government to pay certain sums upon the accomplishment of certain desired results respecting a deep-water channel. Time has proved the jetty system, as applied to the mouth of the Mississippi, to be a splendid success; for, to use Mr. Eads' own words, "the last survey made the channel deeper than ever before, and all doubt of the success of the jetties has been removed." The use of jetties, as a means of contracting the flow of river currents and forcing the scouring out of channels through shallows or bars, is an old plan well known to engineers; but it is the nice judgment which perceives the conditions under which that method may be applied that ensures success. The large practical experience of Mr. Eads with the peculiarities of the Mississippi fitted him to deal with the difficult project he undertook and achieved so successfully.

The presence of this successful engineer in California is full of interest. It is well known that the law of the State, passed in 1878, creating the office of State Engineer, provided for the appointment of two consulting engineers, who were to advise with the State Engineer upon plans for the improvements of rivers and kindred matters. Gen. Alexander and Col. Mendell were appointed consulting engineers; but shortly afterwards Gen. Alexander died, and the vacant place was, by the advice of those most deeply interested, tendered to Mr. Eads. Now that the State Engineer is assisted by such eminent talent—Mr. Eads' mind especially must be a storehouse of facts relating to such matters—we may confidently look for plans which will lead to the speedy opening of our rivers and the practical settlement of the vexed question of drainage. Such a consummation is earnestly desired.

DEMAND FOR LOCOMOTIVES.—We learn from the *Railroad Gazette* that the Baldwin Locomotive Works, Philadelphia, are now employing 2,750 men, all working as full time as the weather will permit. During the past half year they have turned out the largest amount of work ever done in the same time. Upward of 260 locomotives have been sent out in six months, and the orders already entered warrant the assertion that the last half of the year will show a still further increase on what they have hitherto been able to accomplish. During August they will ship 12 locomotives to Australia, besides street motors. They have quite a number of motors under way, including 4 for Brooklyn, 6 for San Francisco and several other cities. Indications seem to show that in the immediate future there will be a larger business in railway equipments than has ever been known.

Caving of the Hudson River Tunnel.

On the morning of the 21st inst., owing to carelessness in adjusting the air-lock, the caisson leading to the entrance of the tunnel at Jersey City caved in, carrying with it an immense quantity of earth; the water from the river flowed in and 20 of the workmen were drowned. The official report of the disaster says:

Twenty-eight men were in the tunnel when the accident occurred, of whom 8 escaped and 20 were drowned. The cause given is that probably the men did not watch the brick wall of the working shafts as closely as they should. The accident will stop work for three weeks. No other points in the official report not already covered. When eight men had gotten out, another of the workmen, in trying to pass through the door leading from the air-lock into the temporary chamber of the tunnel, was jammed in the doorway, and despite the efforts of those ahead, could not be brought out, as the door closed upon him and held him fast. Peter Woodland, Assistant Superintendent, told the men to try and get out, and when the ninth man was fastened in the doorway, he called out to those who had escaped, telling them to hurry up and try to get assistance to help the rest and himself, saying he would stay and make every effort to get the rest out, and if it were not possible, then those escaping must try to get the rest and himself out alive. Following is the complete list of the saved: Thomas Brady, B. McGovern, A. J. Moline, Thomas Cummings, Chris. Hansen, J. Van Nostrand, John Doyle, James Hayes.

The following graphic account of the disaster is given by J. Van Nostrand, one of the rescued workmen: The main shaft is 60 ft. deep, and from the bottom of this shaft the entrance to the tunnel is effected through a cylindrical barrel 6 ft. in diameter and 14 ft. in length. This is called an air-lock, and serves to preserve the density of the atmosphere of the tunnel, which, in turn, is secured by the forcing of air through pipes from the pumps. There is a door in each end of the air-lock. They both open inward. At each side of the doors are round windows of thick glass, through which, from the outside of the air-lock, a view can be gained of the work and the workmen inside the tunnel. There were 23 men at work at the tunnel. They went on at 12 o'clock last night, for the eight-hour shift. I was at work near the east end of the lock, and in the west end of the tunnel, at about 4:30 o'clock, I heard bolts snap and braces give way. At the same time I felt a rush of air on my face. I started back with seven of the men who were near me, and ran into the lock. The air-pressure crowded the door shut at the east end. At first, it was locked by a joist, which we pulled out, and then the door slammed to. Through the dead-eyes we could see the men inside the tunnel. The water was fast rushing. Peter Woodland, Assistant Superintendent, stood at the door outside the lock, which was stationary. It would not move with us without knocking out the dead-eyes. This would be fatal to the men outside, as the water would rush in and drown the men in an instant. Woodland knew this, but stood at the door. His face was ghastly white and he realized the terrible danger. He said to me, "Tom, quick; bust the dead-eyes and do what you can for us." I knew that it was death to us all if I did not, so I obeyed the order. As the glass broke, the air rushed in, and the lock shot out in the main shaft, leaving the men to drown, as the space occupied by the shaft filled with water in an instant. We were wholly stripped of our clothes when we crawled out. I heard a rush of water at our back. It filled in fast, but the obstruction kept it back long enough for us to escape from the main shaft. It was all we could do to save ourselves. Woodland was standing in water up to his waist when I saw him. It was a sure death, and I had to knock out the dead-eyes as I told you. He knew as well as I that it was all over with them. I shall never forget the look on his face, or the sound of his voice, as he told us to save ourselves, though the very act was to insure his death.

In accounting for the disaster, officers of the Tunnel Co. say that the workmen in coming through the air-lock must have been criminally reckless in leaving both doors open at the same time, by which the compressed air was permitted to escape. The compressed air serves a double purpose, namely, to keep the water out and to support the roof, so that when it escaped a catastrophe was inevitable.

The dispatches say the workmen were busily engaged during the afternoon of the 21st inst. in fitting up a powerful pump for the purpose of drawing off the water from the well-like structure, and also for drawing water out of the tunnel, which is filled to the extreme limit; as has been ascertained by engineers by the test of attempting to force compressed air into the cavity. The water in the shaft has fallen about 10 ft. since morning in consequence of the receding of the tide. Every now and then the surface in the center would be disturbed by numerous air bubbles, and at times would appear as if boiling. This appearance, it is said, is due to the fact that some of the earth or masonry is falling constantly within the tunnel, and the displacing air produced this effect.

Engineers and officials say it is impossible for any of the imprisoned workmen to be alive, as the water within the whole length of the tunnel is up to the roof, and even above it. The la-

borers who are making an excavation west of the shaft will not, however, cease their labors to get at where the bodies are supposed to be; but it is impossible to force any air into the tunnel, as all which has been forced in, so far, has escaped through the shaft, in which it has made the water leap up two or three ft. above the surface.

Academy of Sciences.

The regular semi-monthly meeting of the Academy was held on Monday evening last, with Mr. C. Wolcott Brooks in the chair.

A collection of new fishes from Monterey bay was presented by W. N. Lockington, on behalf of himself and from Prof. D. S. Jordan. A new flounder, found off Tacoma, Washington Territory, and a species of bull-head fish, were also presented.

Mr. Lockington read a paper on "The Fish of the Pacific Coast Waters," which was interspersed with very interesting comments on the fishes presented, and gave a synoptical statement of the very important and thorough investigation now being prosecuted by Prof. Jordan on behalf of the United States Census Fish Commission. He reported that

Forty New Species of Fish
Had been discovered upon our coast, many of which would furnish rich material for future description. As our adventurous fishermen are resorting to new grounds, in deeper water, their more recent catches include new species, not previously encountered when fishing in shallower water and nearer shore. He said that it is now ascertained that upon our coast there are known to be 240 species of marine fishes, 40 to 50 fresh water varieties of fish, and some seven or eight kinds recently introduced from the Atlantic coast by portage across the continent, such as Eastern shad, king carp, cat-fish, etc.

He described a sun-fish seven ft. long, and about as high as long, occasionally found in Monterey bay, a specimen of which—fourteen inches long—is now at Woodward's Gardens. Also, a large globe fish, able to inflate itself and float off before the wind at a rapid rate, when tired of swimming.

Twenty-one Species of Flat Fishes,
Resembling flounders in shape, are found on the coast. The halibut is largest, and the haddock is found farther south. The next in size is sold as turbot, and the balance is mostly classed by fishermen as soles. The cods of this coast are unlike those found East, the mouth being differently formed. The so-called rock-cod and ordinary codfish are unlike, and belong to entirely different tribes of fish. Of the 25 varieties of rock-cod on this coast, there is great variety of form, but constant of color. Several species of the true codfish are found around the coast of Alaska and its adjacent islands, where they are as plenty as in corresponding locations upon the Atlantic, but none are found south of Puget sound. They are caught and salted for use in this market, and the industry, which is a growing one, is great as the present demand for consumption will bear.

The Salmon Species,
So well known to us, were described, and so mackerel, several varieties of which are found in the Pacific, but being fond of warm waters, they rarely venture north of the sub-tropical regions of Point Conception. Occasionally a few stray into Monterey bay, but none ever venture into the band of cold water that stretches along the coast abreast of San Francisco bay. Monterey, being middle ground, has the richest supply and variety of fishes of any point on our coast, being resorted to by herons from both northern and southern waters. There is occasionally found at Catalina island a rose mackerel, a Spanish mackerel and a few real, true mackerel, in addition to the albacore, which are plenty.

Mr. Lockington explains that the reason for finding so many new species along this coast was because fishermen have been seeking new deep-water fishing, and have, therefore, and so many fish which have hitherto been strangers to our market. The speaker referred to the whiting in particular, which was until recently a rarity; but latterly, it is seen in abundance at the fish market, and is of a larger species than that formerly sold. A small "tope" (*Galeomus galeus*) was presented, and the speaker explained that it was abundant along the coast, particularly near San Luis Obispo. It has hitherto been believed to be entirely confined to European waters; but it is a source of revenue to the Chinese fishermen of San Luis, who catch these eels, from six to 12 ft. long, and extract the oil, amounting to 12 pounds in a large fish, while the fins are preserved and sent to China. The speaker mentioned another variety of the finny tribe, commonly known in Europe as the king of the herrings. Prof. Jordan has ascertained that this voracious sea monster, which is seldom seen out of the deep water of the ocean, exists in our waters. It eats quantities of herrings, living almost entirely upon them, hence its name. The speaker concluded by saying that Monterey bay was the richest collection point on this coast, as it seemed to be the dividing point between the southern and the northern waters. Here all the species of the northern seas and all of the south are found.

A New Piscatorial Emigrant.

Mr. Keeps, of Alameda, presented what is popularly known as a king crab, the only one ever found on this coast. Its presence here was said to have resulted from its transportation, while very small, across the continent with Eastern oysters, that had been brought here and transplanted, the crab having been found near the San Leandro draw-bridge, and not far from the oyster beds. The king crab greatly resembles the ancient form of trilobites, especially when young, and is the most ancient living species of the crustacean order.

A Peculiar Fish.

Prof. Jordan reports having caught a large fish, in whose stomach he found another fish, just swallowed, inside of which he found still another smaller one, like a nest of boxes three deep, beautifully illustrating how the larger fish swallow the smaller.

Mr. Lockington's remarks were exceedingly interesting, and are of value to scientists and commercial men, as well as to epicures.

A large number of valuable works, among them the recent Smithsonian Institute publications, and also the usual scientific exchanges, were presented and added to the library.

A Hillside Scene in China.

Our illustration presents a scene in the Bohea tea district, of China. We introduce it as illustrative of the system of hillside culture, which prevails in that part of the world. Now that the utilization of our elevated lands is being urged on the ground of their cheapness, and their adaptation to certain growths of fruit, it is interesting to note an illustration of actual work on similar elevations. All are more or less familiar with the cultivation of hillside in Europe for the production of grapes, olives and other fruits, and it is interesting to face the other way and behold hillside ranches in China. The time will doubtless come when our own hillside, with their peerless climate and pure air, and their fitness for certain uses, will be peopled with an industrious and intelligent population. It is an end to be hoped for, and the tendency in that direction at the present time is worthy of all encouragement.

NO "ROYAL ROAD" IN MINING.—Several weeks ago we received from a writer at Volcano, Amador county, an account of a wonderful instrument discovered by a Dr. Wells for finding veins of gold and silver hidden ever so deep beneath the surface. "This magnet," as the writer calls the instrument, "is suspended by a cord from the hand. If there is a gold-bearing ledge underground, the magnet makes a rotary motion, the circle described being large or small, according to the richness of the rock." The same magnet indicates the presence of silver ore by a "vibratory motion." After reading this brief description, we are convinced that Dr. Wells' magnet would lead to success in Gerolstein, but we are doubtful about the result among the hard-headed miners of this coast. What would our correspondent do if one offered to sell him, let us say, a receipt for the philosopher's stone? We hope he would keep his money in his pocket. There's no "royal road" to the gold and silver imbedded in the earth. For us, the pick against the "magnet" all the time. That ancient and useful tool, especially when guided by the best experience, which is simply science, will certainly open the way to the quartz vein. As there is no attempt to explain the wonderful properties ascribed to this magnet, we are left to infer that it possesses an inherent gold-and-silver finding quality. Dr. Wells does not need to sell his magnets. There lie the ground from Arizona to Dakota, holding doubtless countless veins of gold and silver; and if he lacks or desires either or both, let him rotate and vibrate his "magnet" until he becomes a ten-fold millionaire.

NEWS FROM THE "CORWIN."—The U. S. revenue cutter *Corwin*, which some weeks since was dispatched to the relief of the exploring steamer *Jeannette*, as well as the ice-bound whalers, arrived at Ounalaska on the 3d of June, after a boisterous passage of 12 days. The *Chronicle* gives the following extract from a private letter written by one of the *Corwin's* officers on the 7th of June: "We have 100 tons of coal on board now, and will sail to-morrow morning for the islands and the north. We hope to be at the straits by the 15th inst., and will push through into the Arctic on the first opening of the ice. We are all prepared for a winter in the Arctic, having enough stores on board to last all hands 14 months. At St. Michael we will procure two dog teams and add a quantity of salt fish to our provisions. The indications are favorable for an early opening in the ice. The past winter was mild and the spring stormy. Heavy winds are said to break the ice and open the Arctic earlier than clear, fine weather, which is usually accompanied by a very low temperature."

MINING NEWS ASSOCIATION.—An association for this object is the latest thing in New York. It is organized for the purpose of receiving the latest and most authentic telegraphic reports of million shipments, new strikes and other important matters pertaining to the leading districts and mining centers of the country.

Melbourne Industrial Exhibition.

In relation to the approaching International exhibition at Melbourne, Mr. Thomas B. Pickering, who is the accredited Commissioner of the United States, has furnished this account to the *Alta*:

There are several disadvantages to be contended against. Primarily, of course, the enormous distance between any port in this country and the port of destination for goods. Again, this is the first International exhibition abroad, of any importance, for which our Congress has made no appropriation for the transportation of goods, and a third difficulty is the extraordinary business revival among the Eastern manufacturers. It has placed them in such a position as to render it difficult for them to send exhibits to a foreign exhibition. Notwithstanding these circumstances there will be about 400 exhibitors in the American department at Melbourne, and the wares to be exhibited have been selected principally on account of their adaptability to the wants of the Australian colonies. The distance is too great, and the expense too heavy, to send goods merely to show. Our main exhibits will be of agricultural implements and tools, railroad appliances, and silver-plated wares. Among the largest exhibitors are the

ucts to the value of \$92,072,500; the U. S., during the same period, having sent but \$7,000,000 worth of her products and manufactures. These figures demonstrate what business awaits us there if we only introduce our goods and adapt them to the requirements. The same class of goods that were required on this coast, say 25 years ago, for the development of this country, are now needed in the Australian colonies, which are growing with a wonderful rapidity. American exhibitors need not fear that a local prejudice will stand in the way of their obtaining merited awards. At the Sydney exhibition, of 300 American exhibitors, nearly 200 received awards. Exhibitors are charged nothing for space; their only expense is the transportation and installation of the goods, and the U. S. Commissioner will look after and exercise a general supervision over such goods as have no special agents or representatives in charge of them. The Pacific Mail Company has very liberally offered to return to this U. S., free of cost, all such goods as remain unsold at the close of the exhibition. Most of the goods from the Eastern States are being transported by sailing vessels direct to Melbourne, from New York or Boston. Such goods as have not already been forwarded, must necessarily be sent by steamer, and for this purpose special rates have been secured by the Morris European Express, of 50 Broadway, New York city, who also attend to

SCENE IN THE BOHEA TEA DISTRICT OF CHINA.

Ames' Agricultural Co., the Middleton Plate Co., Simpson, Hall, Miller & Co., and Manning, Bowman & Co. Edward Miller & Co. will make a handsome exhibit of lamps, lanterns and bronzes, and the Bradley & Hubbard Man'g Co. of lamps and chandeliers. The American Watch Co., of Waltham, Mass., who received the highest award for American watches at the recent Sydney exhibition, will again be well to the front at Melbourne. The State of Connecticut is making a special collective exhibit of the numerous industries of the State, in a business and systematic arrangement. The most promising exhibitors from this coast are the San Jose Fruit Packing Co. and the Oregon Packing Co., of Portland, the latter sending a fine collection of canned salmon. We have ample space for a magnificent display, having 60,000 square ft., and the American section is admirably located, being directly opposite France and Germany, on the main aisle. Here on the Pacific coast, where our manufacturers and producers are in easy and direct communication with Australia, this exhibition will undoubtedly prove of immense benefit to those who take advantage of this opportunity to present their goods upon the Australian market.

A few statistics may serve to show the importance of the trade of Australia. In the year 1876, the latest date for which the full returns are available, the commerce of Australia amounted to a total of \$462,950,000, the imports of Victoria, the colony of which Melbourne is the capital, being \$78,520,000, and the exports \$70,970,000. In the same year Australia took British manufactures and prod-

ucts to the value of \$92,072,500; the U. S., during the same period, having sent but \$7,000,000 worth of her products and manufactures. These figures demonstrate what business awaits us there if we only introduce our goods and adapt them to the requirements. The same class of goods that were required on this coast, say 25 years ago, for the development of this country, are now needed in the Australian colonies, which are growing with a wonderful rapidity. American exhibitors need not fear that a local prejudice will stand in the way of their obtaining merited awards. At the Sydney exhibition, of 300 American exhibitors, nearly 200 received awards. Exhibitors are charged nothing for space; their only expense is the transportation and installation of the goods, and the U. S. Commissioner will look after and exercise a general supervision over such goods as have no special agents or representatives in charge of them. The Pacific Mail Company has very liberally offered to return to this U. S., free of cost, all such goods as remain unsold at the close of the exhibition. Most of the goods from the Eastern States are being transported by sailing vessels direct to Melbourne, from New York or Boston. Such goods as have not already been forwarded, must necessarily be sent by steamer, and for this purpose special rates have been secured by the Morris European Express, of 50 Broadway, New York city, who also attend to

the speedy forwarding to Melbourne of belated exhibits. During my stay here (which will be until the next Australian steamer, on Ang. 1st), I am anxious to meet and confer with intending exhibitors, and my headquarters will be with H. A. Gregory & Co., Nos. 2 and 2½ California St. The Melbourne exhibition will open on the 1st of Oct., and will remain open for six months—a peculiarity being that it will be the first International exhibition to keep open in the evenings. The Commissioner-General is Mr. George Collins Levy, of Melbourne.

Mr. Pickering has had great practical experience in the matter of exhibitions. He represented the U. S. at the Paris exposition in 1867; at Vienna in 1873, and represented the State of Connecticut at the Centennial. At the Paris exposition of 1878, he was Superintendent of the American machinery and agricultural department, under Commissioner-General Richard C. McCormick, who, Mr. Pickering says, was the most efficient Commissioner the U. S. have ever sent to an International exhibition. In 1873, Mr. Pickering received from the Emperor of Austria the decoration of the Order of Franz Josef, and in 1878 he received from the French government the Cross of the Legion of Honor.

Letters from the Comstock.—No. 4.

EDITORS PRESS:—The Savage men have had their election, and Gen. Williams will be at the helm for another year. When Jim Keene went in several years ago, he promised the stockholders that there would be no more assessments, yet everyone recalls how regularly these calls for coin came. Ever since the water broke in from the west country, the Savage has been an utterly useless piece of property. It has been a rapacious devourer of wood, and whole forests have been swallowed up by the insatiable furnaces, which really amounted to so much money thrown away. There is but one way to work the Savage, and that is through the combination shaft. Let the water come in from the west country until it rises to its level in the shaft, or bulkhead the drifts; then abandon the present workings and use the combination shaft. With a map of the old workings constantly before him, a superintendent need not tap any of the present drifts or crosscuts, and much unexplored country could be prospected. Unless this can be done there is very little use of keeping the pumps running, for no matter how low the water is, the heated vapors rising from the pump will always render the place disadvantageous to work in, and miners must be salamanders who can live there now. It is well known that men have died there from the heat of the incline. Frank Oshiston warned the management of the water before they struck it, and yet they went right ahead until they rushed upon their own destruction. The Hale & Norcross and Gould & Curry might also be worked upon the plan I have proposed. It is not a new idea. The superintendents have talked of it frequently, but it is not a popular idea. It would throw a good many fat-salaried men out of employment, and that is why it is not popular. No Comstock paper has ever dared to advocate it, and the workmen, who know where their bread is buttered, never think of endorsing it. The fact, however, remains the same, that the three mines named can never be successfully worked until they are closed down at their shaft and worked through the combination shaft. A good many miners have held on to Savage, because only a few hours before the rush of water, some miners working in the east drifts came upon ore, and they confided the secret to their comrades. It is not hard to find miners in Virginia, who believe that there is ore yet to be uncovered in Savage, and those who so believed have held on to the stock with a grip that even the regularity of assessments cannot shake off. Here is where many hold one of Coll Deane's three bonanzas lies, but for further information you must ask Coll himself.

The report of the Union Con. recently made contains the statement that the bulk of the ore body lies south of the Sierra Nevada line. Since the line was shifted to suit the convenience of the manipulators, it has been the policy of the inside to bolster up Union and depreciate Sierra Nevada. Yet it is a well-known fact that the bonanza firm is loaded down with the latter stock. They were heavy purchasers at \$200 a share, and despite the way in which the mines have been handled Mackay pins his faith in the unexplored region north of the Union line. He believes the Comstock to be shaped like a codfish, with his big head lying up by the Geiger grade, and his tail in American Flat. Speaking of the tail brings one down to the poor little despised Quinn, owned by Dr. Bronson. The mine is getting to be quite prominent of late, and there is no doubt but that the owners have found a mighty good thing. It is generally believed that there is lots more in the district. There are a good many experienced mining men who hold that the Comstock pinches out near Gold Hill; is poor and thin at American Flat, and then begins to bulge again in the Quinn vicinity. The Lady Brynn men have concluded to sell their machinery, and it is probable that a good many more mines in the Flowery district will follow suit. The only ore in that section is base, and the rich body found in the North Bonanza can only be mined with difficulty, and has as yet been of no use to the stockholders.

The Union pump is advertised to start up on Wednesday, which means, of course, any time this week.

HAND DRILL.

Virginia City, July 21, 1880.

ERUPTION OF AN OLD VOLCANO.—An account from Escuintla, Guatemala, of June 29th, gives some particulars of the sudden eruption of the volcano Fuego de Antigua, which had been quiescent for the past 19 years, and is the volcano that destroyed the city of Antigua, the old capital of Guatemala. The account says that a column of flame shot up to the apparent height of 1,000 ft. and imparted to the sky a bright yellow tint. The crater, which was fully half a mile wide, seemed to labor in discharging the dense volume of ashes, flame and sulphurous smoke. As the eruption occurred on a saint's day, the people of Escuintla regarded the eruption of the volcano as a warning and they all repaired to the church where the service began at 5 o'clock in the morning. An hour later the volcano was not visible on account of the smoke which enveloped it, but the flames at the top were plainly visible. At 8:30 o'clock the ashes and stones began to fall into the river at the base of the volcano and caused columns of steam to rise. The volcano and the surrounding hills were inhabited by Indians, and unless they had been forewarned the loss of life among them must have been great.

The Freeland Concentration Works.

In our last issue we gave a brief description of the Freeland mine at Idaho Springs, Clear Creek county, Colorado; we now give a particular account of its reduction works, and its method of cheap concentration, from a pamphlet published by Aaron Frost:

This mill has been in operation about eight months, and is eminently successful, the only drawback being a lack of sufficient capacity to treat more than one-third of the ore which could be taken from the mine. The capacity is 115 tons per day. The dimensions of the building are as follows: jig room, 75x62 ft.; ore floor, 48x35; engine and boiler floor, 35x43. The dumping floor is 55 feet from the mouth of the Freeland tunnel, which is the avenue for every pound of ore taken from the mine. The crushing machinery consists of two Blake crushers, 7x10 inches in size, and three pairs of Cornish rolls, each 14-inch face and 22 inches in diameter. The sizing appliances are eight revolving screens, in pairs, the first two sizing the mineral in a dry state, the last six being supplied with water, and another ingenious device for sizing the finer mineral. The separation of the ore from the worthless rock, or concentration of the coarser mineral, is effected by 12 Hartz jigs, and the finest material, the slime, is divided into pure ore, seconds and tailings, by a rotary circular buddle. From the dry screens the coarser particles are returned to the central pair of rolls to be re-crushed, and the finer material is passed down to the wet screens, where it is sized for the jigs. The jigs, like the screens, consist of two sets, counterparts of each other. Each set turns out four sizes of dressed ore, and each jig four grades, the whole forming, when placed in phials and labelled, an interesting representation of the efficiency of the Hartz jig. This is a highly scientific process, and its success depends in a great degree on the amount of "bed" carried in each jig compartment and the quantity of water used.

The refuse, designated "tailings," is usually considered worthless. In the case of the Freeland, however, where every thing is worked on a large and economical scale, it is proposed to work the tailings over again and save as much of the \$3.17 per ton that they contain as human ingenuity can do. For this purpose the company has recently purchased a piece of property at the foot of Trail run, where a 15-stamp mill will be erected, and the tailings subjected to that mode of treatment. Four circular buddles and six jigs will also be used at that point. This is about two and one-half miles from the mine, and the crushed ore tailings and slimes will be run down a flume to the point mentioned, where there is an abundance of water.

The cost of concentrating the Freeland ore is 70 cents per ton, the mineral being reduced 60% during the process. The cost of hauling to the railroad is one dollar per ton. Nine men on each shift are all that are required to run this mill. Four cords of wood, at an expense of two and one-half dollars per cord, are consumed daily. This supplies steam for the motive power and for drying the concentrations. The engine is 100-horse power, and the boilers have double that capacity. The boilers are fed by a No. 3 Knowles pump, and a No. 5 pump of the same kind is used for returning the water from the settlers to the concentrators. Once in 24 hours all the machinery of the dressing works is carefully inspected, and a full supply of water and hose, and a Cameron pump are kept in readiness in case of fire.

The cheap concentration of our ores is a matter of vital interest to this district, and at no other place is the business conducted so extensively, thoroughly and cheaply as at the Freeland.

A LUCKY PROSPECTOR.—The Gold Hill News relates this incident: This spring a man came from Canada to the Comstock. He did not know quartz from granite, failed to get work here and at last joined a small company of prospectors on their way to Red canyon. He could get no "partner," for he knew nothing about prospecting; hence he took to the hills, disconsolate and alone. In wandering one day he came across some dirty-looking stuff, and in crossing a strip of 15 or 20 ft. in width, picked up and pocketed four or five pieces of this rock, thought no more about it, quit and came back. His relatives in Virginia, some 10 days ago, in going through his prospecting duds, found this rock. An assay of the whole averaged \$302.85 in gold and about \$2 in silver. This man returned to the lode and found and located the ledge, and is happy. His friends are happy, too, for they have the extension. It is thought to be the mother lode of that section, for which so much search has been made.

AN OLD LOCATION.—Lone mountain, Nye county, Nev., says the *Bentonian*, where recently some valuable mineral discoveries have been made, proves to have been an old location. A party, while prospecting out there this spring, discovered, half a mile north of the Wide West, an ancient hole in the ground. Although this remarkable shaft was only three ft. in depth, still it was a *bona fide* location. In the hole were found a pick and shovel—that is, what the elements had left of them—and a notice of location was discovered near by securely protected between two flat rocks. This notice is dated October, 1860, nearly 20 years ago, and the location had been made by Mexicans.

A MINIATURE RAILWAY.—The shortest and most profitable railway in the world, is probably to be seen at Coney Island, the famous suburban summer resort for New York persons. This is the "Marine railway" which connects the Manhattan Beach Hotel and the Brighton Beach Hotel. It is 2,000 ft. in length, is laid with steel rail, and has a handsome little station at each end. Its gauge is three ft. Its equipment consists of two locomotives and four cars, open at the sides and having reversible seats. A train of two cars is run every five minutes, and at quite a rapid rate of speed, a flying switch being made at each end. The cost of this miniature road, including stations and equipment was \$27,000, and it paid for itself in a very few weeks after it was opened for business. The operating expenses are \$30 a day and the average receipts are \$450 a day this entire season, \$900 being sometimes taken in. The fare charged is five cents. The road runs quite near the water at high tide, yet leaves an abundance of space for those who prefer to walk. It is owned by the same parties who own the New York and Manhattan Beach road, chief among whom is Mr. Anstin Carbin. The property paid a profit last year of 500% on its cost.—*Railway Age*.

DIVING IN A MINE.—In March last an accident occurred at the large pumping engine at Ladymoor, worked by the South Staffordshire Mines Drainage Commissioners, says the *Colliery Guardian*, by which the lower portion of the bottom lift became disconnected and fell to the bottom of the shaft. As it was found impossible to raise the fallen portion, weighing 8 tons, by ordinary means, it was decided to employ a diver, and one from Essex was sent for. He succeeded in finding the lower portion of the lift at a depth of 100 ft. under water. This he safely attached to the capstan rope, by which it was raised. The engine was then very quickly re-instated, both time and expense having thus been saved. As this experiment succeeded so well the same man has again been called in during the week by the Commissioners, to give an estimate for removing the pumps now under water at Stow Heath. The object sought is the removal of the pumps and the engine to some more suitable place. The diver has descended the shaft, and, after hearing his report, the engineers are now considering the advisability of carrying out the scheme mentioned.

RED SNOW.—On the 25th of April there fell in the French departments, Basses-Alpes and Isere, an abundant snow strongly tinged with red dust. The red matter was so abundant that from Barcelonnette all the mountains looked ochrey up to 2,800 to 3,000 meters. Above this the snow remained quite white. A Notary of the place had a quantity of the snow collected, and, after fusion and filtration, sent some of the dust to M. Daubres, who found in it a large proportion of carbonate of lime; also mica and two feldspars, one of them being orthoclase. The powder, then, had probably a terrestrial and not a cosmic origin; but it appears not to be volcanic, like the ash which has sometimes fallen in Scandinavia after Icelandic eruptions; it also differs from the sand of the Sahara, often carried great distances by winds. The point whence it came is still uncertain, but it is interesting to note that the same kind of substance had fallen in 1846, precisely in the same departments, and in 1863 in the Eastern Pyrenees. Showers of similar dust seem to have fallen in Saone-et-Loire on the 15th of April, and in certain parts of Algeria on the 24th.

STEEL RAILS IN GERMANY.—The mean duration of Bessemer steel rails is, according to experiments made in Germany, about 16 years. On the other hand, 10 years of trial between Cologne and Minden have shown that the renewals were, during that period, 70.7% for fine-grain iron rails, 66.3% for "cementation" steel, 33.3% for puddled steel and 3.4% for Bessemer steel, indicating that the latter would last about 16 years. There are, however, some faults found with this description of rails. The engineers of the Kaiser Ferdinand Northern railway contend that Bessemer steel is less capable of resisting concussion, and that when sudden friction has caused heating of the rails with rapid cooling from snow, injurious molecular changes occur.

NICARAGUAN CANAL SCHEME.—A Washington special says: The projectors of the American Nicaraguan canal scheme are here and are much encouraged over the success of Capt. Phelps, who was sent to Europe to confer with the foreign friends of the enterprise, to see what prospect there was of obtaining European capital. The information from Capt. Phelps is that his mission has been successful, and that he will return about Aug. 1st with the financial interests of the scheme ensured.

DRILLING GLASS.—Stick a piece of stiff clay or putty on the part where you wish to make the hole. Make a hole in the putty the size you want the hole in the glass, reaching to the glass, of course. Into this hole pour a little molten lead, when, unless it is very thick glass, the piece will immediately drop out.—*Design and Work*.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenurets, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated, 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Post-paid, \$2. Published and sold by Dewey & Co., S. F.

COFF'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Post-paid, \$1.00. Sold by Dewey & Co., S. F.

A New Edition.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. 1880. A valuable and carefully written work. Postpaid, \$3.00. Sold by Dewey & Co., S. F.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By **ROBERT GRIMSHAW, Ph. D., M. E.,**

Member of the Jury on Wood-working Machinery at Paris Exposition of 1875.

This thorough work, impartially written in a clear, simple and practical style, treats the saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, ash, Mulay, jig, drag, circular, cylinder and band saws, as now and formerly used for crosscutting, ripping, scroll cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,
624, 626 and 628 Market Street, Philadelphia
March 10 1880.

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Muffles, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.
Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.
Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

W. BRUCKNER'S ROASTING FURNACE

AND

Ore Pulverizers.

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.

The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps. Furnished also in sections for packing.

For circulars and prices apply to

Machinery.

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Oblongating Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucibles, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,550.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1887.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 150 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$3.00 coin, postage free.

OX YGEN.

What is it? Everybody knows it is as essential to life as food itself. Yet when people are ill for the very want of revitalization through respiration, they dose themselves with drugs and bitters to the effect of demoralization! All Invalids should read Dr. STARKEY & PALEN'S (Phila.) Treatise on Oxygen, which is sent free to all who may ask for it. The subject is worthy of investigation. References to physicians in San Francisco, who use and prescribe Compound Oxygen in practice. As prepared for home use (conveniently sent to any address) it may be obtained of H. E. MATHEWS, 606 Montgomery street, S. F., upon the same terms as furnished by Dr. Starkey & Palen, Philadelphia, Penn. Complete instructions with each package.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 25th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco

507 Mechanical Movements.

Every mechanic should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & CO., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$1, (post paid.

Notes from Plumas County.—No. 2.

Greenville District.

Mining around Greenville has been active the present season. During the past two years a large amount of capital has been invested in the mines of this locality, now giving a most encouraging showing in finely developed properties. The Crescent mine, situated at Crescent mills, six miles from Greenville, after paying \$800,000 in dividends, and yielding a gross amount of not less than \$1,500,000, in sinking to the depth of 180 ft., for reasons not ascertained, has not been worked for some time. From a brief interview with the Superintendent, it is understood that the company expect to commence operations about the 10th instant (July), with the intention of lowering a new shaft to the depth of 200 ft.

The Green Mountain.

One of the most prominent mines of this section, is also located at Crescent Mills, and most admirably situated for economical working. The property is now controlled in New York. Prior to its purchase by Eastern capitalists, over \$750,000 had been taken out. The main adit tunnel is in over 1,800 ft., and still running through a fine ore body, giving an average width of 10 ft. All the ore is mined and milled, paying \$10 per ton. The present pay chute is 18 ft. wide and 600 ft. long, and is an aggregate of backs in levels Nos. 4 and 5 of 710 ft. Tunnel No. 5 is now in good ore and within 200 ft. of the main pay chute above, which was 16 to 40 ft. in width and 500 ft. in length. Tunnel No. 6, now in about 100 ft., will strike the lode 600 ft. below level No. 5. The mouth of this tunnel is about 50 ft. higher than the base of the new 60-stamp mill now in process of construction, and situated a short distance below. The mill will be completed in about 40 days, and will be run by water power. Weight of stamps 800 lbs. The ore from the lower tunnel will be dumped directly into the mill; that from the upper levels will be conveyed by wire tramway.

The gross yield of the mine for the month of June, with a run of 32 stamps, 450 lbs. weight, 22 days, amounted to \$10,000—the working expense for the month, including dead work, being \$2,600, leaving a nice margin for profit.

The Plumas National.

In the vicinity of Greenville, is also the property of New York capitalists. The mine is represented to be finely developed, and in excellent order—the vein a true fissure, giving evidence of great depth. The main pay chute is over 400 ft. in length, one of the longest in the country. The mine is opened by two levels, giving over two years of ore in sight for the present mill capacity. A third and lower tunnel has been started that will give 300 ft. more of hacks when the vein is reached. A fine 30-stamp mill is running on the mine, connected on a level with the lower tunnel by a substantial tramway.

The company are now building chlorination works for the purpose of working the sulphurets, which are said to be inexhaustible, and giving assays from \$40 to \$50 per ton. True concentrators will also be soon provided for the mill. The mine is thoroughly equipped with a fine plant, and gives promise of rich returns to its owners.

The Gold Stripe Mine

Is another of the fine promising properties in this district. It is situated on Wolf creek, about six miles from Greenville. The substantial improvements and other indications here give evidence of the value of the mine, and of the confidence of its owners in its future. It has now a linear extent of nearly one mile; has been worked for more than three years, turning out in that time a very large amount of bullion. The lode is from 10 to 20 ft. in width, the whole of the ore being extracted and milled, and giving a yield from \$6 to \$10 per ton—the Goodwin portion having given the past year a yield of \$40,000. The ore is free milling and easily worked. It is conveyed to their fine 24-stamp mill by a tramway connected with the lower tunnel. Under the very economical management of Mr. Staudart, the present Superintendent, the average cost for mining, handling and milling of the ore does not exceed \$2.50 per ton; and that taken from one portion of the mine near the surface, leaves the mill with a clear profit of all over and above \$1 per ton. Your correspondent remembers of only one instance coming under his notice on this coast where rock working as low as \$2.50 per ton was made to pay a small profit. Here is an instance worthy of being noted where \$2-ore could be made to yield \$1 profit. Of course it is seldom where the facilities for handling and other conditions are found so favorable as in the case just cited.

The Cherokee Mine,

Near the Round Valley reservoir, is now being put in condition for active operations as soon as the necessary works and hoisting machinery (now on the ground) are erected. It has recently come into the hands of New York capitalists; has a good past record—a large amount of money having been taken out before work was stopped by the burning of its hoisting works. The company have a 16-stamp mill and water power, with capacity for 100 stamps. It is understood also that the Indian Valley and Union mines, consolidated, have passed to

new owners, who contemplate operations at an early day. On this property there are two 24-stamp mills, which will add much to the prosperity of the district when they commence running.

The Bullion Mine,

Near Greenville, on the Big Meadow road, is now being reopened, having been put down a number of years ago to water level. It has been worked more or less in a small way, and some gold extracted from time to time. Hoisting works are about to be put up and work commenced in earnest. Free gold is visible enough in the surface rock without the aid of spectacles.

The Savage, two miles south of Greenville, is down 150 ft. Four men are engaged taking out 36 tons daily. It yields in their 12-stamp mill from \$7 to \$8 per ton.

There are also in this vicinity a number of other promising mines, such as the Antelope, the New York and a few prospect claims which hid fair soon to come to the front.

In addition to valuable mines on one hand and the rich farming lands of Indian valley on the other, Greenville boasts of a substantial foundry, with machine shop complete, capable of turning out machinery as large as is demanded in the country—now building the 60-stamp mill alluded to for the Green Mountain company. It is a neat and orderly town, with a few fine residences, a bank, two good hotels, four large mercantile stores, and all the appointments of a thriving place, giving evidence of being one of the most prosperous towns in this upper country.

With many thanks for information and other favors from Mr. E. Prowatt of the bank, Mr. A. R. Bidwell, superintendents of mines, and others, I remain, as ever yours, etc.,

A. C. K.

A California Songstress.

Madame Jennie Boyer and Samuel Fabian announce a joint benefit concert at Dashway Hall, in this city, on Thursday evening, July 29th. We desire to give this announcement something more than a mere passing notice, for Madame Boyer is one of our most promising San Francisco vocalists. She has recently returned from Europe, where she has spent three years under several of the most celebrated European masters—two years at Milan, where she took a thorough course of instruction in concert, opera and oratorio music, and one year in London studying English and Irish ballads.

Madame Boyer has a soprano voice of great sweetness, purity and power, and it is confidently predicted by her many musical friends, in this city and elsewhere, that she will attain to great eminence in her profession. Her late concert at Dashway Hall was one of the musical successes of the season, fully answering the expectations of her friends, who three years ago encouraged her trip to Europe.

Before leaving Milan she created quite a furore in the vocal world of Europe, as a most promising debutante. The *Milan Gazette* spoke of her in the highest terms of praise. She also attracted much attention in the musical circles of London. The London papers spoke highly of her powers as a vocalist, and much disappointment was felt at her refusal to accept of any of several permanent engagements which were offered her in that city—one of which was tendered her under the auspices of the great composer, Sir Julius Benedict. She was extremely anxious, after a three years' absence to return for a short season to her California home and friends. Mrs. Boyer's manner is extremely pleasing and natural; her voice almost faultless, and there is every indication that she has a brilliant musical career before her. At her coming concert, in addition to Mr. Fabian, she will be supported by the best talent in the city.

We would also mention in this connection that Mrs. Boyer has kindly consented to sing at a concert to be given on Monday evening next, July 26th, for the benefit of the Union Square Baptist Church, in this city, of which church and congregation, she, with her husband, Mr. L. W. Boyer, has long been a member. On that occasion she will also be accompanied by Mr. Samuel Fabian, and supported by other musical artists of note. The concert will be given in the auditorium of the Church.

DEATH OF A VETERAN EDITOR.—A few days since the telegraph announced the sudden death of George Ripley, one of the oldest and most distinguished members of the American press. He "died in his chair in his library," hued with his last breath in his labor of love. Mr. Ripley was associated for years with Horace Greeley on the *Tribune*, and he continued his arduous service as literary editor of that journal up to the instant of his death. Apart from his responsible connection with the *Tribune*, Mr. Ripley was best known as the chief editor of the *American Encyclopedia*, a work which bears the impress of his fine original and catholic spirit. Among his many admirable traits, his sweetness of temper was conspicuous. Whitelaw Reid's eloquent mention of the veteran's death is like a shout of victory: "Full of years and of labors he passed away, as he would have wished, after a serene and honored old age, in the city of his adoption, with family and friends about him, doing his favorite work almost to the end, and dying in his chair in his library."

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

GEOGRAPHICAL GAME CARDS.—Walter G. Read of Epperson, Colusa county, Cal. Patented July 13, 1880. No. 229,914. This invention consists in the employment of a number of cards equal to the number of States and Territories in the United States. At or near the center of each card is drawn, in a distinct color, the State or Territory from which the card derives its name. The suits are designated by the line of latitude passing through or near the State or Territories in that suit, and the value or rank of each card in a suit is determined by the population, which is marked upon one corner, while the figure designating the value or rank of the card is marked upon its face in a large light-line figure, the same figure being also marked of a small size in the upper left-hand corner. These cards are intended for the purpose of instruction, at the same time while they are being used in playing games such as are played with ordinary cards.

SASH FASTENER.—Noah Haynes, San Jose, Cal. Patented, July 13, 1880. No. 226,884. The object of this invention is to provide a means by which the window-sashes of cars, steamers and houses may be made tight and dust-proof in their frames or stops, while at the same time they may be readily raised or lowered or held at any point without liability of jamming. It consists in providing pivoted stops in the frame inside of the sash, which stops are held in contact with the sash by means of a strong spring, the spring being controlled by a lever or knob. The sides of the sash and of the stops are provided with corrugated rubber bands, so that by engaging with each other the sash will be held at any desired point.

Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions rendered upon patent cases in litigation, for the benefit of our readers:

DECISIONS OF THE U. S. COURTS.

Hoe et al. vs. Cottrell et al.

U. S. Circuit Court, District of Connecticut. Decided March 23, 1880; Shipman, J.

1. The first claim of the patent granted March 16, 1880, to Richard M. Hoe, as assignee of August H. Marioni, declared to be for a patentable combination and sustained.

2. The burden of proof is upon the defendants to overcome the *prima facie* case made by the patent and to establish affirmatively that the party upon whose application a patent was granted was not the sole inventor of the improvement covered thereby.

3. Where M. and C. jointly took out foreign patents, and M. sole subsequently made application for an American patent, which was granted, the testimony of C. that he is a joint inventor with M. controverted by that of M., will not serve to invalidate the patent in the absence of proof of admissions by the latter of joint invention in either of the foreign applications.

4. The decision of the Commissioner of Patents upon the fact that an applicant had complied with the requirements of the statute with regard to his application, and that certain acts were properly done, such as that the drawings and model required by statute were presented, or that an attorney by whom amendments were made was the duly constituted attorney of the applicant or his assignee, or that the specification had been sufficiently sworn to by the inventor, is not to be reviewed collaterally. If the patent is invalid by reason of any or all of these defects, its invalidity is to be determined in a proceeding to set aside the patent by *scire facias*, or by bill or information.

5. Although from the standpoint of after time it might seem difficult to see that a particular combination of old elements should be the exercise of invention, still the fact that in the multiplicity of prior machines in the same line of invention a combination of such value had not been hit upon, and that when introduced its utility was universally recognized, renders it evident that in order to make such combination changes were necessary which the skill of the mechanic would not suggest, and that the work was practically more difficult than to the theorist it might now seem.

6. In determining the question whether there was invention in any particular combination, the important point is to ascertain whether novelty and utility existed. It is true that these requisites may result from mere mechanical skill, and a new and useful combination may be formed by the mere mechanical addition of an old element to an old set of members; but when a device has a new mode of operation which accomplishes necessary results, "looks with favor upon it," and is not exacting as to the degree of inventive skill which was required to produce the new result. There must be some, but a little will suffice.

7. A claim introduced upon amendment which includes an element additional to the combination of which the invention is stated in the body of the specification to consist, is not void where such additional element is shown in the drawing and described in the specification, although not there mentioned as one of the elements of the invention of the applicant.

Banker vs. Bostwick et al.

U. S. Circuit Court, Southern District of New York.—Decided June 14, 1880; Wheeler, J.

1. Letters patent, No. 43,371 granted June 23, 1864, to Banker and Carpenter, assignees of George W. Prince, for improvement in the manufacture of tin cans, sustained.

2. The invention covered by the patent upon which suit was brought, and by that set up in defense being dependent upon certain peculiarities of form and position of parts of operation, which a comparison necessary to consider the drawings in connection with the specifications, and to rely upon the drawings alone to some extent to ascertain the exact form and position of some of the parts.

* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

THE LITTLE PITTSBURG.—According to late reports from Colorado this notorious Leadville mine is coming out well after all that has been said. Explorations are being pushed in various parts of the property and though no nodules of ore so extensive and rich as those formerly worked have yet been struck, much that is worth working has been reached and more is likely to be.

News in Brief.

CHASTINE COX, who murdered Mrs. Hull in 1879, was hanged at New York, July 16th.

At Manchester and other towns in New Hampshire there was a lively earthquake July 20th.

SOME extensive sulphur beds are being opened up at Cove creek, and shipments will soon be made.

THE French government has ordered an agricultural course in every primary school in the country.

MR. BRADLAUGH has been pronounced by a leading English judge to be one of the best lawyers in England.

A WINNEMUCA (Nev.) man says that plowing ground and turning sheep on it destroys the grasshopper eggs.

COMPLETE editions of Bulwer and Scott are sold on the Nassau street, N. Y., second-hand book stalls for \$1.50.

GARDEN concerts and public dancing are patronized in Berlin by high government officials and society leaders.

MOST of the cities in Virginia have fallen short of public expectation in the census, Richmond having 75,000.

BIG Cottonwood lakes, Utah, are now to be seen in their greatest beauty, and tourists are gathering around them.

TEXAS gave this year its largest yield of wool, 1,300,000 hales of cotton, and an unusually large crop of corn.

THE French Chamber of Deputies voted a credit of 9,000,000 francs for the construction of the Sahara railway.

THE Mormons are taking possession of San Luis Valley, southern Colorado, and have built a town called Manassah.

THE *Coast Mail* says that lately a dog went into the surf between Port Orford and Ellensburg and caught a fur seal.

A RUSSIAN priest was fined and banished for stating from the pulpit, that the entire nobility of Russia is tainted with Nihilism.

At a public meeting in London a protest was entered against the erection in Westminster Abbey of a statue of the Prince Imperial.

A ROBIN has built its nest in a railroad switch, near a New Hampshire station, directly under the signal light, where 25 trains pass every day.

At San Antonio, Texas, July 20th, Gen. Trevino and Miss Ord, daughter of Gen. Ord, were married in church in the presence of 2,000 people.

IN point of wealth the Elberon colony, Long Branch, is almost equal to Newport. It is said that six members represent thirty millions of dollars.

THE wheat crop of Napa county is larger than was anticipated, and the grape crop is expected to be the largest ever harvested in the valley.

THE necessity of raising the grade of the water front of Portland Or., is being discussed in consequence of the late overflow by the Willamette river.

OXFORD tutors are described as less revered by their pupils than formerly, but more in harmony with them and better companions than they used to be.

THE New York employment agencies report that there has been no such demand for labor, both skilled and unskilled, for numbers of years as there is now.

BULLS must be kept tied up this summer, otherwise the country will be dangerous for people who carry the Turkey-red calico parasols now so much affected.

THERE are in New York city 85 Episcopal churches and chapels, the number having doubled in 25 years, and 24,000 children in the Episcopal Sunday-schools.

COACHING has been revived at Newport in all its original glory, there being several members of the coaching club there. A grand parade of the drags is promised in August.

A NEW ORLEANS lady procured, a year ago, over 2,000 silk-worm eggs, from which she raised 2,000 cocoons, and from these she has obtained more than 80,000 eggs.

A new style of "society youth" has appeared at the seaside. He allows his hair to grow long, hnsbee it behind his ears, and refuses to talk upon any topic but decorative art.

THE St. Petersburg Society of Naturalists has given 1,000 rubles each to the two exploring expeditions which go this summer to Lapland and the Mourman coast of the White sea.

THE report that the Russian government will shortly prohibit the exportation of corn is semi-officially contradicted. Statements in regard to the failure of the crops are greatly exaggerated.

NOW that pockets are out of fashion in ladies dresses, hags of various kinds are coming in vogue, and one may expect to see before long some lady carrying a hag like that of the Widow Bedott.

A CHICAGO man makes a living by finding lost articles. He goes to public gardens, parks, etc., every morning before daylight, and looks for anything which persons may have dropped during the previous evening.

MILLE GREVY, daughter of the French President, has received from one of the Siamese Ambassadors in Paris, as a gift, a dress of a peculiar make and material always reserved for royal wear in his native country.

AT Phoenix, Arizona, watermelons are coming in in large quantities. In a few days sweet potatoes will be in the market, and peaches, grapes and figs will be plentiful by the 1st of August, all raised within a few miles of Phoenix.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, Its Formation and History." This
very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing sec-
tions, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & Co., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SLEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

With Adjustable Out-off Poppet Valve Engine, and Forced Iron Crank Shafts.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

Office, No. 230 California Street, - - San Francisco, Cal.

STEIGER & KERR'S
CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

SECURE PATENTS

Through Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

Wanted—An Obelisk.

Obelisks, monoliths, Cleopatra needles, exhumed from the deep oblivion of the centuries, have come into modern fashion. It would appear that the fashion came from Egypt, and the old vagrant monoliths of that country are now in vogue. Paris and London, and now New York, each can point with pride to its obelisk. California needs one. We need one, not to minister to a puerile vanity, but rather to gratify the landable feeling of a proper State pride. We need one to help keep fresh the memory of the most interesting incident in our history. Finally, we need an obelisk to perpetuate the memory of a man whose name will be forever bleuded with the recollection of that incident. Let us raise an obelisk of native granite as a monumental memorial of the discovery of gold in California. That fortuitous incident sharply accented the history of the State, and the enterprise of the pioneer Sutter was the immediate cause of its occurrence. We believe the pioneer societies of the State could not engage in a worthier cause than the erection of a monument for such a purpose. It should be undertaken at once.

There can be no question of the high significance to California of the discovery of gold through the operation of Sutter's enterprise. It goes for nothing that the discovery was purely accidental; that it was simply a happy incident. The discovery of gold at Sutter's mill site did undoubtedly change the early destiny of California, which, but for that incident would not, in all human probability, have differed from that of Kansas or Oregon. Grant that it was an accident; yet it was a fresh thread in that endless web, "woven in the roaring loom of Time," which has more or less changed the pattern of our State. It has redounded to the glory of California, and has done more to achieve her remarkable progress than all the other occurrences in her brief but splendid history. The distinction which California has acquired throughout the world arose, chiefly, from her profuse gold, and to this day California and gold are as intimately associated as Newcastle and coals or France and wine. It may be said that her material wealth and fame are the result of the accidental discovery in April, 1848, of gold at the site of Sutter's saw mill, at a point on the south fork of the American river, long since known as Coloma, in El Dorado county. It would be a slight thing to commemorate such an important event by the erection of a simple monument of stone. Not to do it would be, it seems to us, an omission of grave import to the character and dignity of the State.

It may not now be possible to determine the precise spot where the old sawmill stood. It has long since decayed or has been destroyed, and so far as can be learned every vestige of the work has passed away. But while the exact spot may never be determined, it is now possible to indicate an area, not of great extent, inside of which it can be proved that the mill stood. Indeed, we learn from a writer in the *Georgetown Gazette*, that the site of the mill can be absolutely traced within a radius of 250 ft. All doubt respecting the precise location of the Sutter mill might be removed by embracing a radius of say, 500 ft., or even 1,000 ft.; then let this tract be enclosed as a State park, and in the center erect a granite column, bearing a simple and proper legend, as a memorial monument of the discovery of gold in California. And there let it stand and share the destiny of the great State. Such a monument would fitly commemorate the golden era of California. No learned archaeologist would be required to interpret its legend, for it would tell the marvelous story to every child. It would be an obelisk that we would have pride in and delight to cherish.

THE NATIONAL PARK.—The (*Montana Miner*) says: "Unless an Indian scare or a war breaks out within the next month, the great National Park—the paradise of sight-seers and the finest hunting ground on the continent—will be visited by hundreds of people from Montana alone, to say nothing of those who will come from the country at large.

LIVELY TIMES IN CALAVERAS Co.—According to the *Chronicle*, mining affairs are very lively in Calaveras county. It says that speculators, mining experts, miners and capitalists are arriving almost daily, and engage in negotiations for some of the many gold-bearing mines that occur all over the county. The recent strikes of rich ore in the Boston, Whiskey Slide and Hoosier, as well as in several others of less note, has increased the interest in the mining property to such an extent that it partakes of an exciting boom. The *Chronicle* mentions the sale to San Francisco parties of a mine called

FIG. 1.

FIG. 3.

PURE AND DISEASED MILK AS SEEN WITH THE MICROSCOPE.

the Baudin, a recent and valuable discovery, and says the new owners intend to work their property immediately, and with vigor. We record these results with pleasure, and hope that the miners of Calaveras and of every other mining county will continue the work of developing their mines, so that men of capital will be induced to examine and buy them. Real, tangible mining property will always command a remunerative price.

CHINESE MINERS.—We learn from a trustworthy source that a company of Chinese is engaged in mining on a very extensive scale on Big Indian bar, on the middle fork of the Feather river. The parties recently purchased a claim of very rich ground there, and are now engaged in building a flume 22 ft. wide and over 400 ft. long. It is said that the ground has hitherto paid well, and is likely still to be productive.

Milk Under the Microscope.

From a pamphlet on milk production recently published by Mr. R. G. Sneath of this city, we reproduce several engravings showing the distinction between healthy and diseased milk as seen by aid of the microscope. The drawings are by Prof. R. U. Piper, of Chicago, who has made prolonged studies of the subject. Fig. 1 is healthy milk. Milk appears under the microscope as if made up of innumerable round globules of varying sizes, floating in a clear or slightly yellowish fluid.

FIG. 2.

FIG. 4.

diseased milk. Fig. 2 is a sample of milk taken from a milk wagon in Chicago. There may be seen some regular globules which are doubtless the true spheres found in pure milk, but there is also a mass of foreign matter which doubtless consists of fungus or animal germs and portions of diseased tissue from the udder of the cow. The appearance in Fig. 2 was gained soon after the milk was drawn. After it was allowed to stand over night it presented the appearance in Fig. 3. Here are seen bacteria, fungi and vibrios, which Prof. Tyndall describes as "long, eel-like organisms, tossing the globules aside, and wriggling more or less rapidly across the field of the microscope." These organisms, that is the bacteria, he tells us, are the agents of all putrefaction.

Fig. 4 is another sample of diseased milk. It was taken from the food of a sick child in Chicago, the milk being supplied by cows fed on distillery swill. The microscope showed it to be filled with uncleanness and diseased matters, and when the food of the child was changed to pure milk it recovered from its illness speedily.

The evil character of the milk which is furnished to city people from swill-fed cows, results, it is believed, in two ways. It may be produced by the introduction of ferments, which enter the blood of the animal from the unhealthy food, and it is also the result of the diseased condition of the udder which accompanies such improper diet. The danger of partaking of poison in their milk always overhangs people who use milk from dairies fed upon distillery or brewery refuse. There is also a diseased condition produced in milk by cows drinking stagnant and foul water, which should always be guarded against both in city and country. It has been proved by the experiments of Prof. Law, of Cornell University, that cows drinking water from impure pools—water containing fungus germs—will have these low vegetable growths conveyed into the circulation, and from the blood transmitted to the milk; that, although the milk did not at first show any signs of the fungi, yet, on standing, it turned out to be bad, and on microscopical investigation, the same fungus vegetation found in the water appeared also in the milk. The cows, too, on examination were found to be affected in health, though to a casual observer they might not appear ailing. The microscopical examination of milk from swill-fed cows has shown not only fungi, but particles of pus, and there can be no doubt that serious troubles have come from partaking of such milk.

The chemical composition of milk made from swill-fed cows is also of interest in this connection. As compared with the composition of pure milk it shows marked variations. We give below an analysis of milk from distillery-fed cows of New York, as follows:

Water.....	93.0
Butter.....	1.3
Caseine.....	3.4
Milk sugar.....	0.7
Salts.....	0.1
	100

Now, milk of average quality has the following composition in 100 parts:

Water.....	87.40
Butter.....	3.43
Caseine.....	3.12
Milk sugar.....	5.12
Mineral matter.....	0.93
	100.00

It will be seen, in comparing the two tables, that the swill-milk contains not only 6% more water, but is sadly deficient in butter and milk sugar.

PERSISTENT EARTHQUAKES.—Since the 18th inst., severe earthquakes have been continuous on the island of Luzon, the chief of the Philippine group. At Manila, the capital city, the destruction of life and property has been very great, and the inhabitants had fled to the fields for refuge. The earth had opened in many places, from which jets of steaming water or showers of ashes were ejected. All the volcanoes on the island were in a state of violent activity. Manila has suffered terribly from earthquakes. One occurred in the middle of the 17th century, by which 3,000 people are said to have perished; in 1832, an earthquake nearly destroyed the city; and another in 1865, caused the loss of several thousand lives.

The other engravings show the appearance of

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EWS

Mining Around Reno, Nev.

EDITORS PRESS:—Mining in this vicinity is confined chiefly to Peavine and Pyramid districts. Each locality shows rich specimens of ore, a varied assortment of the finer and baser metals, some very high assays and several good working tests. The lodes are of good working size, some of them large and well defined, but only a few as yet opened to any considerable depth. Lying as they do in the very shadow of the great Comstock lode, their just merits may have been somewhat eclipsed, and less capital come in on this account. That they are inviting fields for investment, the following facts, gleaned in the neighborhood, and presented as concisely as possible, may be some evidence in corroboration:

The Mines of Peavine District

Extend from the immediate vicinity of Reno for many miles to the northwest—the best developed, and some of the most promising, being within 10 miles of the Central Pacific railroad, and directly on the line of the late survey for the Oregon road, making them very accessible. The surface and surroundings of this whole region give decided indications of its mineral-bearing character. Gold, silver and copper are all found here, sometimes in combination with sulphurets of iron, lead and other base metals.

Two miles north of Reno a ledge (42 ft. in width), of a seemingly valuable mineral point, has been discovered—a fine weather-proof article—pronounced by painters here equal to the best "Prince Metals."

The Paymaster,

A base metal mine (ledge 30 ft. wide), has been opened by a shaft to the depth of 150 ft. The rock has worked by chlorination all the way, from \$80 to \$150 per ton. In connection with this ore there is a large body of lower grade that will pay well by concentrating the sulphurets.

The Poe ledge, on which are several locations, has had working tests as high as \$86 per ton. The Golden Fleece is said to have a good strong vein of eight ft. in width, opened by tunnel and incline, making an aggregate depth from surface of 160 ft. Three miles north of this point there is

A Fine Copper Belt

From which much ore has been shipped, running 40% in copper and about 50 per ton in gold and silver. The Griffin company, made up of citizens of Boston, are now vigorously pushing a tunnel to cut the vein at a depth of 400 ft. from the surface. Eight miles north of these copper mines a gold belt has been discovered, which is now being prospected thoroughly by the Antelope company in particular. They have found six ft. of ore in the lode. The assays for gold run \$30 per ton.

About five miles southwest of Reno is situated

The Mountain View,

A promising claim of carbonate ore, assaying up in the hundreds in silver. Among others here are the Loomie, Reform and Esmeralda Consolidated.

The Unit, owned by Mr. A. H. Barnes of the Golden Eagle hotel, Reno, and other citizens, is a well-defined vein, seven ft. wide between the granite and porphyry, the ore giving free milling assays of \$16 per ton in gold. Arrangements have been made to have 80 tons worked at the Auburn mill near Reno.

The Manselond Mine

Is located three and a half miles from Reno on the western slope of Peavine mountain. A very considerable amount of work has been done here, showing a vein of ore 25 ft. wide, largely impregnated with sulphurets, gold predominating, the whole assays averaging \$25 per ton. The tunnel which is now being driven will be completed within three months, cutting the ledge at the depth of 200 ft. from the surface. It is understood that the company will be incorporated in October, with one-fourth of stock, unassessable, for working capital, and will be duly tested on the Chicago Mining Board.

Pyramid Lake Mining District

Is situated about 30 miles north of Reno and 50 miles from Virginia City. Work commenced, for the first time in earnest, about four years ago. The range for three miles in width is represented to be a porphyry formation, within which are numerous parallel veins. Among a host of locations here, may be named the Buckeye (with a shaft of 150 ft.), the Monarch, the Pyramid Lake (shaft 170 ft.) and the

Jones & Kinkead,

On which about \$50,000 have been expended, steam hoisting works have been erected, and a shaft sunk on the ledge 400 ft. The company had at one time a working test of 227 tons from the 400 level, at the Auburn mill, that yielded \$46. Twenty tons selected and sent to Denver worked as high as \$183 per ton. The full width of the pay vein has not yet been ascertained. They are extracting all the ore for the width of 15 ft. on the 300 level, which is estimated to go from \$20 to \$30 per ton. They have now on the dump about 1,500 tons.

The next mine in order is

The Crown Prince.

The ledge, some 30 ft. in width, was tapped by a tunnel 125 ft. in length. A drift then followed the vein 400 ft., from which 1,000 or 2,000 tons of ore have been extracted, and now lie on the dump. When the ore was first struck three assays were made, the highest giving up to \$1,040 per ton—\$640 in silver and \$400 in gold. The course of the main ledge through the district is north 25° east, with a dip east of about 25°. Taken all in all, this whole region ought to be looked upon as more than promising.

A. C. K.

Notes from Arizona.—No. 1.

EDITORS PRESS:—I propose to write you now and then from this Territory, and generally from some of the mining points; but as yet I have not been at any of the mining localities, and thus, at this writing, will not touch upon any particular mining developments.

The mass of people cannot fully comprehend the great value of a railroad pushing on into and through a country distant from settlements—into a rough, wild region. And but few, perhaps, who take advantage of such great improvement, fully appreciate its benefits. A railroad is the spirit and life really of all sections of the country, but particularly of Arizona. It is the artery or avenue of a vast region, from which everything must spring, as well as tend to. It admits of people getting into and out of a distant land in comparative ease. It brings machinery, goods and everything needed close to hand. A railroad in Arizona merely gives or offers opportunities for fortune, large or small, to the people. With a railroad, mines can be either sold or worked with profit; without it, the richest deposit would have but little value. But little of the actual mining and business movement of Arizona took shape until it was known that a railroad was certainly to pass through the Territory. The mass of people, even those that have never been to this land, either by rail or otherwise, know of the great desert stretch of hundreds of miles on both sides of the Colorado—a vast country without settlement and without prospect of settlement. And thus can one, in passing over such a country, more fully appreciate not only the value of a railroad to parties having interests beyond the desert stretch, but of the enterprise and nerve that conceived and pushed a railroad over such country to completion.

This city has the reputation of having a warm climate, or of being uncomfortably hot, during a portion of the year. While this, to some extent, is true, yet, thus far in July—as objectionable a month as any of the whole year—the thermometer has not touched above 110°, or not above 110° during the season. This information is obtained at the Signal Service office. The old town of Tucson stands 2,500 ft. above the sea level, and nearly every day there is a fine breeze coming up the valley. The Santa Cruz, a small river, winds around close to town, and along its banks there is quite a little forest of trees and green fields stretching away over the valley, furnish a cheerful and cool appearance to the city.

There seemed to be evidence that in all the mountains of southern Arizona, there is a greater or less deposit of precious metals. In many of the mineral localities, however, but little more has yet been done than to establish the fact of the existence of numerous veins of ore. As to their richness, it will require time and labor to determine. But it may, perhaps, be regarded as a settled question, that up to the present time no other region of equal area gives promise of such vast mineral deposits as southern Arizona seems to possess.

Tucson is the chief city and business point of Arizona, and is also important to a range of country of quite large area across the line in old Mexico. Buildings and improvements of modern style may be seen, surrounded by adobe walls, and activity and enterprise mingling through Spanish-Mexican customs and easy life. Viewed from a point of moderate elevation, the spot appears as if aroused by a vitality that both spreads out and raises up. It was a spot of interest in Aztec times, and was more recently known to us as a city among Indians. In the mountains around where a little time ago the Apaches roamed and ruled supreme, the sounds of industry are common, and settlements are gradually spreading out over the plains and valleys, and mining towns are working up over the mountains.

Tucson, July 15, 1880.

PEARLS IN NEW ZEALAND WATERS.—Recently, says the *Anchor Evening Star*, Benjamin Gittoe had been wandering along the banks of the Oakley creek close to the Whau tributary. He was attracted by a peculiar looking shell-fish in one peculiar sand deposit. He had never seen in the whole of the district (during a period of nearly 20 years) any such shell. He made further search and to his astonishment found a large quantity of the fish, varying in size. On opening a few of them he found that the inner coating of the shell was beautifully covered with mother-of-pearl. He extracted several of the fish, and in those of the larger size found several pearls loose in the shell. They have a strange formation and color, not perfectly round, but far more brilliant than those found in the South Seas. He has ten in all which have been pronounced of great value.

California Chrome Iron Ores.

Mr. G. W. Gesner, writing to the *Oil, Paint and Drug Reporter*, gives an interesting description of the location of the chrome ore mines of California, which promise to become the basis of an important industry. Chrome iron ore is found associated with serpentine rock in many parts of the State of California, but owing to lack of transportation facilities, only those of San Luis Obispo county are available. Five miles from San Luis Obispo, on the San Luis Obispo & Santa Maria Valley railroad, is a group of mines extending along a line of two miles, covering an area of 400 acres. From them 15,000 tons have been shipped within the past three years, part of this quantity going to Europe and part to the Eastern States. So far they have merely been prospected, the quantity mined being insignificant in comparison with the quantity to be had. La Trinidad, La Esperanza and El Salto can alone supply any requirement of the trade for years to come. The town of San Luis Obispo, five miles away, with its railroad station, is in the valley 1,800 ft. below the mines, and the roads from the mines clearly traced leading to the main road to the town. Ten miles further away the Pacific can be seen, and in clear weather the Coast Line steamers coming into Port Harford, the shipping port of San Luis Obispo.

Any process for the manufacture of bichromate of potash requires the skill of persons accustomed to chemical operations on a large scale. The usual result in weight that may be looked for from 2,000 lbs. of chrome iron of 50% oxide of chromium is 1,600 lbs. of bichromate of potash. The extent of the manufacture and use of bichromate of potash in this country can be seen from statistics of the trade, which give for the year 1879: Import of bichromate, 2,624,000 lbs.; domestic manufacture, 4,258,000 lbs.; total, 6,882,000 lbs. During the year the price averaged 13 cents per lb., making the total value for that time \$894,660. So far in 1880 the price has averaged 14 cents per lb., with an increased import and a greater domestic production. The chief use of bichromate is in dyeing, in the production of the variety of colors and pigments in which chrome plays such an important part, and in charging batteries for telegraph purposes.

THE QUINN MINE.—We are informed by the *Enterprise*, of the 21st inst., that some remarkably fine specimens of silver ore have recently been taken from the 200 level of the Quinn mine. Among these is a large mass of ore, one side of which is covered with flakes of native silver. This native silver is as bright as a new dollar. In a cavity about the center of the same piece is a small nugget of metallic silver of the same kind. Other pieces of ore are filled with ruby silver and stephanite, and in some are seen, in the same piece of rock, black sulphurets, ruby silver, bright native silver and stephanite. These would make very handsome and valuable specimens for a cabinet. North of the shaft, on the 200 level, a winze is being sunk in the vein. This winze is now down some 15 ft. The material from the bottom of the winze is being hoisted and saved for crushing. The average assay of this is \$102.72. The average was obtained by taking a sample from the top and bottom of each tub of ore. Where they are now at work is at a point where there are no croppings and no sign of ore seen on the surface. The south drift will presently pass under the place where the top of the ore chimney came to the surface—the part where Mr. Quinn for so many years did his surface mining. In that direction something better is looked for than has yet been seen.

HIGH MINES.—The Lake City (Colorado) *Silver World*, says that a tourist over the range from the head of Poughkeepsie to the valley of the west fork of the Animas river, sees when he reaches the summit, near the Mountain Queen mine, a smooth, bare slope of bright yellow rock, the summit of which is 13,200 feet high. This is California mountain, and on its crowning ridge stands the Nevada cabin, a house above the clouds, built of the yellow rock of the mountain. It was built in 1876. The mines which lie on California mountain are named the Virginia, San Francisco, Nevada and Crown Point. The owner intends to work all the mines named. The Virginia carries gray copper, silver sulphuret and glance, which assays 90 ounces silver per ton, and mill runs have yielded from 100 to 110 ounces. The ore has never run less than 40 ounces, and from that up to 500 ounces. Specimen assays from the Nevada lode have run from 75 to 400 ounces. The Crown Point is an extension of the Virginia and the ore is similar to that of the Virginia. The San Francisco is also an extension of the Virginia, and shows the same class of ore.

ACTIVITY IN CALAVERAS.—As an indication of the great activity in mining in Calaveras county, and the interest which has been awakened to that industry, the *Citizen* says it has taken the trouble to ascertain the number of locations of mines which have been recorded in the office of the County Clerk during the past six months, and finds the number to be 325. This certainly looks as if the quartz ledges of Calaveras county were not to have much repose.

THE Egyptian obelisk arrived at New York, July 20th.

A Siam Sapphire Mine.

The term sapphire is usually restricted to clear crystals of bright colors used as gems; while dull, dingy colored crystals and masses are called corundum, and the granular variety of bluish-gray and blackish colors is called emery. Blue is the true sapphire color; when it is of other bright tints it has other names; as Oriental ruby, when red; Oriental topaz, when yellow; and Oriental emerald, when green. Sapphire is pure alumina, and next to the diamond it is, in some of its varieties, the most costly of gems. India, Ceylon and the East, where most of the precious stones are found in abundance, are the parts of the world where the largest number of sapphires have been picked up, from among the pebbles into which the floods have washed them out of the clay. Of recent years, says the *London Echo*, we have heard of the new find of diamonds in Southern Africa, which soon became noised abroad because the locality was near to British colonies. Now we learn through a consular report of a great find of sapphires, the knowledge of which has taken five years to reach this country. A native hunter in Siam came upon a locality, very remote and secluded, which proved to be rich in sapphires. Some men, who immediately followed him, returned to Rangoon and Calcutta with stones which realized large sums. Then came a rush, and thousands of British subjects from Burmah passed through the capital of Siam on their way to the mines. Some of them found fortune, but many others met with jungle fever and died, while those who survived returned home so emaciated that the temptation to grow rich at such a cost lost its force. Consul Newman, of Bangkok, remarks that each miner has been required to pay a license duty of 5s. 7½d., but the authorities have done nothing to prevent so much wealth in precious stones being carried out of their country. The more fortunate miners are very anxious to conceal their gems while they remain in Siam; but one man of whom the consul knows dug out a stone for which he could not find a purchaser on the spot at £100. Accordingly he went to Rangoon, where he was offered £1,500. This awoke him to its value, and, declining the offer, he went to Calcutta, where he eventually obtained £3,000 for his treasure. The largest stone that has been heard of from the Siamese sapphire mines weighed 370 carats in the rough, and, when cut, 111 carats of the finest water. One consequence of these mining operations is a rise in the value of good looking marriageable young women, in whom the lucky miners are investing.

FOSSIL SHARK'S TEETH.—In excavating for a ditch along the face of a bluff bordering on Kern river, says the *Kern County Californian*, Mr. John Barker recently found a magnificent fossil specimen of a shark's tooth some two inches in length. The enamel was so perfectly preserved that the finely serrated edges of the tooth were as sharp as the teeth of a saw. No bones of this animal were found. Fossil remains of this character are quite common in that section. Shark's teeth by the dozen have been picked up on the tops of the adjacent hills 500 ft. or more above the river. This is a fine field for the geologist. The river has cut down hundreds of feet through the sedimentary marine formation which is thus exposed to view in horizontal strata. Imbedded in the face of the bluff on either side of the river for a distance of four miles below the mouth of the canyon, are huge granite boulders, brought down and left by the glacier that chiselled out the gorge in its present form.

A YEAR'S OPERATIONS AT THE MINT.—Operations at the San Francisco mint, during the year ending June 30th, were as follows:

Value of gold operated on.....	\$54,007,049
Value of silver operated on.....	18,308,483
Silver purchased for coinage.....	7,883,895
Ounces of silver (crude and dore) refined.....	5,682,697
Ounces of gold refined.....	489,335
Yielding in standard ounces, gold.....	524,323
Yielding in standard ounces, silver.....	4,887,351
Fine silver bars manufactured for depositors.....	1,969,947

There remain unexpended of the appropriation for mint expenses the following sum:

Wages of workmen.....	\$22,764.25
Contingent expenses.....	41,162.53
Total.....	\$63,926.78

Which amount, after paying all losses and wages chargeable to those appropriations, has been returned to the U. S. Treasury.

HEAVY PRODUCT OF BULLION.—The Colorado correspondent of the *N. Y. Mining Record*, informs that journal that for the six months ending last June 30th, the product of bullion from the Boston & Colorado Smelting Works at Argo, near Denver, was: gold, \$392,283; silver, \$692,787; copper, \$226,000; total, \$1,311,075. The writer assumes that the shipments of gold and silver for the last half of the year will exceed those of the first half, and that the amount of copper will be about equal. He estimates the product of bullion for the year at the large sum of \$3,000,000.

A GRAVEL STRIKE REPORTED.—It is announced by the *Nevada Transcript* of the 20th inst., that a rich strike is reported to have been made in the Albert gravel mine, formerly known as the Buckeye, near Nevada City. It is alleged that gravel was opened which pays as high as 25 cents to the pan. The fortunate owners of the claim are residents of Grase Valley.

MECHANICAL PROGRESS.

Tempering in Sand and Tempering Chisels.

Color tempering in heated sand is a particularly faulty process. It is impracticable to keep the upper surface of sand heated equally with the bottom sand; indeed, it is almost impracticable to heat the upper surface to redness in the open air, the looseness of the sand permitting the heat to pass off so freely. If sand, heated to redness below, is disturbed, that which comes to the surface loses its redness almost instantaneously; as a result, the part of the steel imbedded in the sand heats too much in advance of the exposed surface, hence projecting parts, such as screw-threads, temper too quickly. If the steel is turned over in the sand, the fine particles of the latter obscure the temper colors, and it is doubtful if the best results can be obtained by the use of sand, no matter how slowly it is heated or how slowly the tempering proceeds.

Heated pieces of flat iron are excellent for flat rectangular pieces of steel. The iron should not be too thick in proportion to the size of the article to be tempered, and should be revolved while laying on the iron, as well as being turned over and over. This is necessary in case the iron should be unevenly heated. The article should be tempered slowly resting on the side, faces and edges alternately, so that the heat may approach the center of the steel from all sides (which will induce uniformity). The piece should be removed for a few seconds, occasionally, from the iron, which will give the heat time to penetrate it and retard the heating of exposed edges or projections of small section.

When an article requires tempering in one part only, it is the usual practice to dip it in that part only, leaving the heat remaining in the rest of the steel to draw the temper of the hardened part, and an excellent example of this process is the common chipping chisel or a mill pick. Chipping chisels require to be tempered to the shade of blue that immediately succeeds the purple tints. The taper of a chisel is usually of such degree that by the time the cutting end has had about 5-16 inch removed by the resharpening, that end will be too thick and must be drawn out, as the reforcing is termed, and the object in the hardening will be to have the temper equal in degree throughout this 5-16 inch, and to have the temper back of that run out gradually, and not suddenly, to normal softness, so as to avoid the breakage that will inevitably ensue if any part of the taper end of the chisel is left harder than a blue, or if the part tempered terminates suddenly.

In heating the chisel it should be frequently turned over and over in the fire, and must be occasionally withdrawn from the fire, so as to see that the thin end does not get overheated (which it is, from its thinness, very apt to do) before the thicker part is sufficiently heated. If the thin end is found to be heating too quickly, it may be pushed through the fire into the cooler coals, or dipped slightly at the point; but this latter plan is always to be avoided as much as possible. The blood-red heat should extend for about one-half inch up the chisel, and the end should be dipped about 7-16 inch in the water and held still for about eight seconds. It should then be dipped suddenly another three-eighths inch in the water and quickly withdrawn. The object of this second and deeper immersion is to graduate the temperature of the steel so that the colors shall appear in a broad band and very slowly, so that when the blue appears it will extend over about one-half inch from the chisel end backward. The colors appearing and changing slowly will afford the eye ample time to determine when the exact proper shade of color has arrived, when the chisel may be dipped and withdrawn several times, so as to cool it and leave it tougher than it would be if cooled right off after being tempered to color.—*Joshua Rose in Blacksmith and Wheelwright.*

Use of Glass for Construction.

The use of glass as a material for construction is attracting much attention in England since the practical application of toughened glass to permanent ways has been successfully made. As we have already noted in these columns, Mr. Bucknell, an English engineer, proposes to manufacture pipes for gas and water conduits, for drains and chemical purposes, as well as building blocks and numerous other articles.

In a late paper read before the Society of Arts of London, an interesting account was given of the remarkable results of the strength of examples of toughened glass; and it was asserted that old as the manufacture of glass is, the various processes of toughening it are still in their infancy, and that it is not unreasonable to look for immense improvements in this direction in the future.

Respecting the manufacture of the toughened glass sleepers, which have attracted so much attention by reason of the novelty of the application, it is stated that the clamps and other metallic attachments, are put in red hot while the glass is still fluid, and that when cold the glass and iron hold rigidly together. There is little to be feared of the cracking of such a joint, as the mutual expansibility of glass and iron differs very little. The cost of this tough-

ened glass is, weight for weight, about the same as cast iron; but as the glass is only about one-third as heavy as the iron, it is evident that for equal dimensions the cost of the glass will be only about one-third that of iron, the ton of glass making three times as many sleepers as the ton of iron, supposing it to be so applied.

But the latest application of toughened glass which has been noted is for the manufacture of types for printing purposes. The London *Pottery Gazette* says: "Some experiments are reported to have been made in France with a view to showing whether this substance can be pressed into the printer's service and substituted for the metal composition of which types are made. This latter does not at first sight strike the observer as the best that could be found. It is bright enough when the letters first come from the foundry, and before they have seen any service; but a few days' wear gives the type a very dingy appearance, and before they are finally returned to the melting-pot they have degenerated into a very squalid form, looking dirty in their body as well as battered in their faces. The idea is now to discard these long-proved but unattractive servants, and fill their places with glittering types of glass. The advantages in point of cleanliness alone would, it is alleged, be not insignificant. The toughened glass, which is not to be made in quite the same way as that used for tumblers and wine-glasses, and need not, of course, be quite so transparent, is naturally much harder than the old metal, and can hardly be crushed out of shape by those little accidents which so shorten the life and spoil the beauty of the only type we now employ. It is also capable of being cast into more delicate shapes, so that the difference, for instance, between the thin and the thick strokes can be more clearly defined. Finally, it is now found that the new material can be cast in exactly the same molds as the old, and that therefore there need be no expense incurred in altering the machines and implements used in the manufacture of type."

MALLEABLE nickel and nickel products are among the novelties produced at the establishment of Dr. A. Fleitmann at Iserlohn, Germany. Dr. Fleitmann, it will be remembered by some of our readers, not long ago made some interesting experiments respecting the action of magnesium on the malleability of nickel and cobalt. He found that the addition of very small quantities of the last-named metal overcame the brittleness of nickel and rendered it far more tractable to manipulation. This he ascribed to the action of the magnesium in removing the oxide and other impurities from the metal. He has since reported the observation that an alloy of nickel, with a small percentage of zinc (about 5%), is to some extent malleable, and may be rendered completely so by the addition of so small a quantity as one-twentieth of one per cent. of magnesium. The product resulting from this treatment is capable of being welded to itself and to iron and steel. Messrs. Fleitmann & Witte are said to have rolled sheet-nickel two feet wide, and to have turned out nickel-plated (faced?) sheet iron or steel. The process is to weld thicker plates of nickel to those of iron or steel, heat the same to the required temperature, and then roll them out together in the ordinary way, which, it is said, may be done without scaling.

HINTS CONCERNING SAWS.—A saw just large enough to cut through a board will require less power than a saw larger, the number of teeth, speed, and thickness being equal in each. The more teeth, the more power, provided the thickness, speed and feed are equal. There is, however, a limit, or a point where a few teeth will not answer the place of a large number. The thinner the saw the more teeth will be required to carry an equal amount of feed to each revolution of the saw, but always at the expense of power. When the bench-saw is used, and the sawing is done by a gauge, the lumber is often inclined to clatter and raise up the back of the saw when pushed hard. The reason is that the back half of the saw, having an upward motion, has a tendency to lift and raise the piece being sawn, especially when it springs and pinches on the saw, or crowds between the saw and the gauge; while the cut at the front of the saw has the opposite tendency of holding that part of the piece down. The hook or pitch of the saw-tooth should be on a line from one-quarter to one-fifth the diameter of the saw; a one-quarter pitch is mostly used for hard, and a one-fifth for a softer timber. For very fine-toothed saws designed for heavy work, such as sawing shingles, etc., even from soft wood, one-quarter pitch is best.

ANCIENT AND MODERN MORTARS.—In hardness and binding qualities the ancient mortars surpass the modern; but the supposition that this superiority is to be ascribed to certain secrets of manufacture, or of manipulation, which in our day have been lost (although this assertion is sometimes made), is purely gratuitous. The true explanation, without doubt, is that all mortars improve as they age, and attain their maximum hardness and strength only after a very long time. This is accounted for by the fact that a chemical union takes place between the lime and the silica of the sand composing the mass, and this is an extremely slow process, requiring years to complete. Comparative examinations of ancient and modern mortars, show that the older the mortar the more silicate of lime it contains, and consequently the better its quality.

SCIENTIFIC PROGRESS.

Quantitative Analysis by the Spectroscope.

The progress made in this direction of quantitative analysis by the spectroscope is summed up by the *Manufacturer and Builder* as follows: Experiments to use the spectroscope for quantitative analysis have been undertaken specially with the view of employing it for the assaying of the precious metals, and they have naturally emanated from the scientific departments of the mints. Such experimental attempts have been reported from W. C. Roberts, of the London mint, and A. E. Outerbridge, of the Philadelphia mint, and the results in both were unsatisfactory, so far as establishing a practical working method is concerned. In both cases, the principle which formed the basis of the experiments, was that first noticed by J. Norman Lockyer, a celebrated English spectroscopist, "that when a powerful induction coil is used, and the distance between the metallic electrodes is gradually increased, certain of the lines of the spectrum break in the middle; and that on further increasing the distance between the electrodes, the hiatuses in the spectrum lines increase proportionally, until the lines themselves finally disappear." Mr. Outerbridge, whose experimental investigations of this subject were very exhaustive, found, in his attempts to found a working quantitative method of analysis on Lockyer's discovery, that the method was defective in the extreme. He reports that the differences between the spectra of two alloys of considerable difference in constitution, were very slight; and where the alloys approached closely in composition, the spectral differences were quite unappreciable. A difference of one-1,000th, for example, required an effort of the imagination to detect. The amount of metal vaporized was found to be too infinitesimal to give safe results on a large scale, since these results would be likely to be vitiated by the slightest want of homogeneity of the alloy. This point will be appreciated when it is stated that the quantity of metal vaporized by each spark was found not to exceed the one-1,000,000th of a grain. Finally, Mr. Outerbridge found that while the spectroscope was very sensitive to pure metals, a comparatively large quantity of gold could be present in an alloy, and the spectroscope would not indicate its presence. In an alloy of gold and copper, for example, containing from 200 to 250 of gold, the spectrum of gold is scarcely visible; and this same want of sensitiveness holds good of other metallic alloys. On these grounds, Mr. Outerbridge has pronounced the use of the spectroscope for assaying to be impracticable.

WIND PRESSURE.—Does the wind, in passing through the open spaces left between the solid members of an articulated structure (such as a bridge), experience no further resistance than that offered by the net area of the solid surfaces of the members? We think it does. Air is a fluid equally with water, and it is well known that when water issues through an orifice in a flat surface, the issuing stream is very sensibly contracted to much less than the area of the orifice. This coefficient of discharge through holes in plates or flat surfaces is as low as 0.62%; or, in other words, only 62% of the opening is truly effective for the passage of the liquid. Without doubt, these principles apply equally to all fluids, gaseous as well as liquids. In the case, then, of air flowing through an articulated structure, we do not think that the full area of the opening, between the solid members, should be considered as effective for the passage of the air, but only to a reduced extent of, perhaps, from 60% to 70%. This would have the effect of adding very largely to the gross resistance offered by any articulated structure to the wind—in fact, it would cause an addition of from 30% to 40% of the openings to be added to the solid members as representing the whole area offering a resistance to the passage of the wind. This additional amount of resistance may be found more than sufficient to occasion overturn, when otherwise it would be far from being anticipated by calculation.—*Iron.*

RESPIRATIVE POWER OF MARSH AND WATER PLANTS.—It is a well-known fact that these plants are able to thrive in media which contain little or no oxygen. They are all very poor in nitrogen, and E. Freyberg has shown, by a number of experiments, that this latter property accounts for the former. His investigations prove that the respirative power of plants varies with the amount of nitrogen they consume, and this, taken in conjunction with the fact that water plants contain large air chambers which do not often need refilling, accounts for their being able to exist in media which contain very little oxygen.

WONDERFULLY SENSITIVE PHOTO PLATES.—Photo plates made by the new photo gelatin-bromide process have such a remarkable sensitiveness that soft harmonious negatives may be secured in one-sixtieth of a second. The opportunities for instantaneous pictures are thus greatly extended. At a recent meeting of the Society of Arts, London, Mr. Gale exhibited photographs in which was shown the picture of a swallow poisoning in the air over a pond, the shadow and reflection in the water being very perfect.

Electrical Insects.

It is not generally known that there are insects which possess the peculiar electrical properties of the *Raia torpeda* and *Gymnotus electricus*. Kirby and Spence, in their entomology, describe the *Reduvius serratus*, commonly known in the West Indies as the *wheel bug*, as an insect which can communicate an electric shock to the person whose flesh it touches. The late Major-General Davis, of the Royal Artillery, well known as a most accurate observer of nature, and an indefatigable collector of her treasures, as well as a most admirable painter of them, once informed me, that, when abroad, having taken up this animal and placed it upon his hand, it gave him a considerable shock with its legs, as if from an electric jar, which he felt as high as his shoulder, and dropping the creature, he observed six marks upon his hand where the six feet had stood. Two similar instances of effects upon the human system resembling electric shocks, produced by insects, have been communicated to the Entomological Society by Mr. Yarell; one mentioned in a letter from Lady de Gray, of Groby, in which the shock was caused by a beetle, one of the common *Elateridae*, and extended from the hand to the elbow on suddenly touching the insect; the other caused by a large, hairy lepidopterous caterpillar, picked up in South America by Capt. Blakeney, R. N., who felt on touching it a sensation extending up his arm, similar to an electric shock, of such force that he lost the use of his arm for a time, and his life was even considered in danger by his medical attendant.

PREMIUM OF \$1,000 FOR SCIENTISTS.—The National Board of Trade passed a resolution, at a meeting held on the 12th of December last, offering the sum of \$1,000, as follows, viz.: \$500 for the best essay and draft of bill on the adulterations of food and drink in the United States, \$300 for the second best, and \$200 for the third. The objects to be kept in view in preparing the essay shall be to show: First, what are the deleterious adulterations of articles of food and drink in this country; second, the effect of these adulterations on health and trade; third, the best means of detecting and preventing their recurrence with the least interference with commerce, and with the least expense to the community; fourth, the reasons for the legislation proposed, is the draft of the laws proposed must be in such form that they can be at once submitted to State legislatures and to Congress for adoption. The different essays must be written in legal form on foolscap paper, the writing to be on one side of the sheet only. The time for completion is limited to the first day of October, 1880. The Committee of Award consists of Dr. John S. Billings, U. S., Washington, D. C.; Prof. Chas. E. Chandler, New York; Ex-Chancellor B. Williamson, Elizabeth, N. J.; A. D. Hardy, Esq., Boston; and John N. Gano, Esq., Cincinnati.

THE PRACTICAL VALUE OF SCIENCE.—"I have endeavored to State the higher and more abstract arguments by which the study of physical science may be shown to be indispensable to the complete training of the human mind, but I do not wish to be supposed that because I may be devoted to more or less abstract and unpractical pursuits I am insensible to the weight which ought to be attached to that which has been said to be the English conception of Paradise—namely, 'getting on.' Now the value of a knowledge of physical science as a means of getting on, is indubitable. There are hardly any of our trades, except the merely bucksterning ones, in which some knowledge of science may not be directly profitable to the pursuer of that occupation. An industry attains higher stages of its development as its processes become more complicated and refined, and the sciences are dragged in, one by one, to take their share in the fray."—*Huxley.*

EARTHQUAKE WARNINGS.—In a recent lecture on the possibility of foretelling earthquakes, Prof. Palmieri expressed the belief that by means of seismographic stations, telegraphically connected, for registering and reporting preliminary earth tremblings, it would be possible to foretell earthquakes just as tempests are now foretold, and to issue warnings to threatened districts about three days in advance. He did not expect to live to see such a system in operation, but he hoped and in a measure expected that posterity would be benefited by its universal and permanent establishment.

THE AMERICAN SCIENCE ASSOCIATION.—The 29th meeting of the American Association for the Advancement of Science will begin August 25th, in the Massachusetts Institute of Technology, Boston. An exceptionally large gathering of prominent scientific workers is anticipated. One of the morning sessions will be held at Cambridge, and the rest of the day will be devoted to an inspection of the various departments and museums of Harvard University and the Observatory.

A CURIOUS EXPLOSIVE.—An alloy of rhodium and lead, lately exhibited before the French Academy of Sciences, has the curious property of exploding on exposure to heat, as in being held before a gas flame. Its composition is one-third rhodium and two-thirds lead, fused together in a crucible, at a high temperature.

Mr. Brown, mining operator formerly of Southern Nevada, has made a pretty thorough examination into several Inyo mining properties. He has bought the Orion

gold mine and little mill at Old Coso, acquiring both the conflicting titles of Fuentes & Co. and that of P. Reddy. He is putting on a force of men and will soon commence shipping gold, having gone into the business on that proposition solely.

KERN.

WHITE RIVER NOTE.—*Californian*, July 22: The best prospecting ground in Kern county, and quite as good, we venture to say, as any in Arizona, is at White river, along the base of the Big Blue mountain. Several gold ledges of great value have been found there lately, and as yet hardly any real prospecting work has been done.

MONO.

LARS DISTRICT.—*Mammoth City Herald*, July 17: In tunnel No. 3 in the Mammoth, a distance of 42 ft has been run, giving a total of 1,174 ft. In No. 2, 29 ft; total, 944. The upraise No. 3 tunnel to No. 2 has been connected and an ore-chute put in. The work of relieving the old winze from No. 2 to No. 3 tunnel has been completed. Number of tons of ore sent to mill during the week, 304. Work on the head of No. 4 tunnel has not yet been resumed, the flow of water continuing unabated. The shaft of the new water race has been raised and the building will be completed during the coming week. The mill is running steadily, with everything in excellent working order.

H. L. & M. C. JOINT TUNNEL.—On Tuesday last the air compressor and the engine which drives it were found to be so much out of repair as to be almost useless. The cylinder-rings in the air-chamber were so badly worn that the air escape and it was difficult to keep pressure enough to run the drilling machine. The rings have been expanded and faced up in the Mammoth Co.'s shops, and the engine put in perfect running order. The work was resumed last evening, and Mr. Crittenden informs us that the whole machine is now as good as a new one.

WHITE MOUNTAINS.—*Bodie Free Press*, July 22: J. Wagner has just returned from the White mountains, 40 miles from Lake District, where he made some good locations. One ledge was uncovered that shows free gold in considerable quantities. The croppings are prominent and the main ledge, he thinks, is at least 40 ft wide. It crowns a high hill; on one side gold is found and on the other silver. Several men are prospecting in that vicinity and are confident of finding something good. The White mountains have never been thoroughly prospected, and it is believed rich veins will some day be opened up. The field is large and inviting.

NEVADA.

NEW MINING CO.—*Transcript*, July 20: A consolidation of the El Capitán, Wheel Jano and Transcript mines in Gold Flat, in this district, has been effected, and reincorporated under the title of the New York and Boston gold mining company, with a capital of \$1,000,000, at \$5 a share. Earle W. Johnson, of Boston, is President, and B. G. Bloss, of New York city, Vice-President. The property of the company covers a longitudinal area of 3,630 ft by 600 wide.

NOTES FROM THE RIDGE.—*Grass Valley Union*, July 21: Hydraulic mining is now being actively prosecuted at all points along the Ridge, the water supply being good, and some of the companies will be enabled to work entirely through the season. At Moore's Flat and vicinity there is much activity in mining, and plenty of water so far to meet all demands. The North Bloomfield mining company is running full handed, and has not yet commenced to draw upon their reservoir of water in their large dam on Canyon creek. Some snow is yet to be seen between Esmeralda and Canyon creek, that will furnish water for that reservoir.

WATER SUPPLY.—There is every promise that the water supply for the up-country mines will be better than ever before known, from the fact of the quantity of snow that fell last winter, and the better facilities now possessed for catching the seepage by means of the large reservoirs in the high mountain valleys.

CHINER NOTES.—*Cor. Herald*, July 22: The English company has commenced sinking a shaft in their mine on Badger hill. They have already reached a depth of 25 ft. This company is composed of energetic men who firmly believe that man cannot replenish his pocket-book at will without putting his shoulder to the wheel with a determination. Nearly 20 men are employed in this mine.

BENNETTS.—The men are engaged in prospecting the Benneville mine, situated at Little Grass Valley, near Columbia Hill, and are pushing things ahead in good earnest.

EUREKA LAKE CO.—This company is having hoisting works erected at its shaft, which is being driven down in the mine known as the Consolidated, situated near the old town site of Columbia Hill. The necessary machinery has been ordered, and it is to arrive soon. A number of experienced miners, with whom I have conversed in relation to this project, say that it is evident that good results will come from it, and the entire Ridge benefited thereby.

A RICH STRIKE.—*Transcript*, July 25: Several years ago some parties ran a tunnel on Gold flat to drain a ledge they owned. After advancing some 200 ft they quit there. Recently Messrs. Stephens & Vance relocated the claim, and after cleaning out the old tunnel, resumed operations in it. A ledge varying from 8 to 20 inches in thickness was found, and from it were taken 10 tons of ore. This has just been crushed at Keith's mill on the Plaza, and paid \$27 a ton in free gold and about \$3 in sulphurets. The reporter has seen some of the ore, and it shows well in free gold and sulphurets. The size of the ledge and the quality of it increases rapidly with depth.

PLACER.

KINDER MINE.—*Dutch Flat Forum*, July 24: Charles Carr informs us that they are now washing pay dirt that a year ago would average \$2.50 a day with the old styled sluice box and pick and shovel in the Kinder mine. This section has been a good paying one in these diggings. The water is rather low now and work will be suspended in about 1 week. Mr. Carr says he will clean up his sluices and undercurrents in about 2 weeks, and anticipates a good season's run.

A GOOD CLEAN-UP.—*Cor. Herald*, July 24: The Van Esmeralda Bros. have just finished their first clean-up and the way that they piled up the dirt is gladdening. You don't like to see 400 ounces of gold dust in one little pile? If you would, come up and take a peep into their safe—no amalgam or dirt, but clean, bright, pure gold, worth \$19.50 per ounce.

NOTES.—Bill Mitchell has struck the richest kind of gravel, and has a magnificent prospect for a good time. This claim adjoins the famous Rainbow mine. Mr. T. O. Durning, of Iowa Hill, reports the water season at the hill as about ended, and the mines in consequence mostly shut down for the season.

PLUMAS.

BELL MINE.—*National*, July 24: The workmen in this mine have been following the rich ledge for some 30 ft, and most of the time the rock shows free gold. The ledge is 4 or 5 ft thick, and the rich rock is on the footwall. It is beautiful bluish-white quartz, and of a much better quality than in any other part of the mine. On Wednesday the work developed a lot of rich rock, and we were shown about half a pan full of quartz which probably contained \$300 in gold. Many places, where the rock had decomposed, were nearly pure gold, and the whole mass was brilliantly studded with the bright dust. The mill is paying well, and the pay increasing regularly. A bar worth \$1,900 was sent to the Chicago office the other day.

GRAN MOUNTAIN MINE.—This mine is located 16 miles from Quincy, and is owned by a company of New York capitalists. They have 150 men at work and are erecting a 60-stamp mill. Two mills, one 10-stamp and the other 20, are constantly working the rock extracted. The vein varies in width from 12 to 18 ft. It is low grade, averaging \$10 per ton.

SIERRA.

GOOD HOPE EXTENSION.—*Mountain Messenger*, July 24: We visited this property lately and saw that although not much work had been done, enough had been accomplished to show that a very large ledge passes through the claim. Samples of ore taken from a number of places on the croppings will yield probably from \$8 to \$20 per ton. Timber

is plentiful along the large vein, and ample water power can be had at the North Fork, perhaps a mile distant.

PROSPECTIVE WORK.—A Mr. Rouse, from Contra Costa county, has been some time prospecting the old Ohlin and Pomeroy claims above Wahoo. He has a tunnel some 600 ft long and has found gravel that will pay 25 cents to the pan.

NOTES.—There is a great deal of prospecting being done in the neighborhood of Milton since the snow disappeared, and considerable excitement prevails. Work has been started on the Mastodon Con. mining company's property, and the indications met with thus far are quite favorable. All the section of country located on the ridge between Forest City and Gold Lake, a distance of some 30 miles, is now actively prospected. There are probably several hundred claims located within this distance, and work is in active progress upon a large number of them. It is believed by those competent to judge that a gravel channel follows the ridge for the whole distance, and will pay wherever opened.

SISKIYOU.

GRAVEL STRIKE.—*Cor. Redding Independent*, July 17: The last chance, near Calihans, has struck a body of gravel which is paying \$13 per day to the man. They work through a shaft 45 ft deep, using water power for hoisting the material.

QUARTZ STRIKE.—Rich quartz is reported at Six-Mile creek, near the Black Bear mine. Some prospectors struck a vein, and from 25 lbs of rock took \$152.

TRINITY.

BUCKEYE W. & H. M. CO.—*Journal*, July 24: We learn that work has commenced on the last half mile of the Stuart Fork ditch, and that the enterprise will be completed in a few weeks. With water through this entire line of the ditch and completion of their bedrock tunnel, the Buckeye company will be in condition to make a splendid showing with their Bolts Hill property.

TUOLUMNE.

GLARK MINE.—*Cor. Independent*, July 24: This mine is still looking as well as ever. Work on the mill is being pushed forward as rapidly as circumstances will permit. An immense hopper has been built near the shaft, into which the ore is dumped from the car, from whence it will be let into the wagons beneath and taken away.

The 18-crozier of mill in the vicinity of Jamestown are being rapidly developed, and mills and other expensives improvements are going up in every direction—a state of affairs that has already created a demand for good houses in this town.

SONORA ITEM.—We are informed that Adam Haag has placed his sulphurets mine, on Sonora creek, into the hands of a San Francisco company, who will at once proceed to develop the mine, and, with the most approved and latest appliances, for the successful working of sulphurets ore.

NEVADA.

WASHOE DISTRICT.

SAVAGE.—*Gold Hill News*, July 23: The bulkhead on the 2300 level is about completed and ready to close. This will shut the water flowing from the incline from that level, but will not prevent it from following up the incline. There is no opening for it on the 2100 level. It may raise to the 2000 level, and if so, it will either be conducted in pipes to the C. N. S. shaft or will be raised to the 2100 level by the Savage pumps, running at a greatly-reduced rate.

SILVERA NEVADA.—The crosscut east, 1,010 ft north of the incline and on the 2400 level, has been stopped till the water is out of the incline. This will be accomplished by Friday night. The crosscut was commenced to be in readiness when the opportunity should be presented for pushing it ahead.

THE TEXAS.—The north drift on the 2500 level is passing through dry vein porphyry, which needs no timbering and through which the exceedingly rapid progress of 10 ft per day is made.

UNION CON.—Work from winze No. 1 toward winze No. 2 on the 2500 level has been suspended and the men taken out and set to work connecting the drift north and west from winze No. 1 with the station of the Sierra Nevada incline.

CALIFORNIA.—The north drift on the 2300 level is advancing to make connection with the drift south from the Gphir line, and complete the thoroughfare on this level from the C. & C. shaft to the Union shaft. The joint Gphir crosscut east on the 2000 level, from which a winze is to be sunk to the 2300 level, is averaging 3 ft per day.

ATRA.—In about 2 days more the station on the 2050 level of the incline will be completed. The body of quartz struck on this station was from 5 to 6 ft in width and gave low assays.

CHOLLAR.—The flow of water to the C. N. S. shaft from the Hale & Norcross winze and the drift west on the 2400 level continues to decrease.

GPHIR.—The joint Mexican crosscut on the 2500 level is averaging 3 ft per day through the station on the 2050 level of the incline will be completed. The body of quartz struck on this station was from 5 to 6 ft in width and gave low assays.

BECHER.—The diamond drill has been running east from the end of the south drift on 2760 level, and has penetrated porphyry carrying promising quartz, and encountered a very strong flow of hot water which is supposed to come from the same body found east on the 3000 level.

CON. VIRGINIA.—The stopes on the 1750 level are yielding as usual. The joint Best & Belcher winze is going on down below the 2000 level and the south drift on the 2300 level is advancing 20 ft.

BECHER.—The diamond drill has been running east from the end of the south drift on 2760 level, and has penetrated porphyry carrying promising quartz, and encountered a very strong flow of hot water which is supposed to come from the same body found east on the 3000 level.

YELLOW JACKET.—Pump-and-repaired and pumps working well. Yellow jacket ground has been reached in the east drift, 2325 level. The diamond drill is running east in crosscut on the 2700 level, to guard against water.

CROWN POINT.—The drift connecting with the 2525 level of Jacket has been graded down 420 ft, and the drain has been cut 200 ft.

CON. IMPERIAL.—The crosscut west from the foot of the south winze, and on the 2510 level, has attained a total length of 50 ft, and continues in a mixture of quartz and porphyry.

UNION SHAFT.—Cutting out the 4th compartment of the shaft from 5 different points and the tank-pit at the 2500 level. The pump at the 2500 level is running regularly.

OVERMAN.—The incline raise above the 700 level is going on up, and is cutting porphyry carrying seams of quartz.

BECHER.—The diamond drill sent in from the face of the drift on the 2000 level has encountered water and been withdrawn.

QUINN.—Still raising some ore which assays well. Work is going on in the winze below the 200 level.

UTAH.—The incline is 35 ft below the 1950 level. The east drift on the 1950 level is still in hard rock. The ore vein has not yet been reached.

SUTRO TUNNEL.—Both headers are progressing well; total length of north lateral, 3,690 ft; south lateral, 1,440 ft.

AURORA DISTRICT.

THE PROSPECTUS.—*Esmeralda Herald*, July 24: Prospect tunnel No. 1, of the Prospectus, having been thoroughly opened up to a distance of 100 ft, all the way in good ore, work was shut off last Saturday. South drift about 20 ft in rich ore has been reached, and the shaft did not. Work was stopped in the tunnel and in both drifts, for the reason that the ore was all good milling and no dump was ready to receive it. Biased tunnel, located about 500 ft south of Prospect tunnel No. 1, was started up the first of the week. A contract for 200 ft was let, to be pushed night and day until completed.

NORTHERN BELLE.—A drift has been run in 70 ft from the Northern Belle shaft to the south, to open up the American mine. This drift will tap the ledge of the latter mine at a depth of 140 ft. The drift is all the way in the ledge, and the ore is considered good the whole distance. Another drift is being run south from the bottom of the shaft to tap the Northern Belle ledge.

THANKS TO VINO.—The north drift is now in 46 ft, the face

of the drift showing the best looking ore yet found in the mine; the south drift 60 ft, the crosscut 56 ft, which exposes an immense amount of ore. There is 250 tons of ore now piled up on the dump.

GRAND TRUNK.—The crosscut of the Grand Trunk has been advanced 24 ft since our last report, leaving about 10 ft to be accomplished to tap the ledge.

REAL DEL MONTE.—Since last report the plunger pump on the 500 level has been connected and started up, and is now working smoothly.

NOTES.—Win McKinlay and C. E. Winters have leased the McIntosh & Barnes mine, owned by W. P. McIntosh, and commenced taking out ore yesterday. They inform us that the ore is rich enough to make a nice little dividend. By the middle of next month they will send a crushing to the Millers' mill.

BRISTOL DISTRICT.

HILLSBORO.—*Flores Record*, July 17: This Hillsdale furnace is running well and turning out 100 bars a day. Coal and lead ore are coming in fast, and there is every prospect for a long and successful run. The mine is still improving on the 40 ft level, and the ground is improving.

NOTES.—Work was suspended on the Lons Vale shaft, owing to the foul air, but was resumed on the Monarchist, to cut this ledge higher up.

CHERRY OREEK DISTRICT.

MINING NOTES.—*White Pine News*, July 13: The Sadie L. mine, at Silver canyon, has an incline down something over 100 ft, showing a strong ledge of high-grade ore.

COMET M. CO.—Mr. John Reese has been appointed Superintendent of this company's property, and has a force of men at work on the mine. The Comet company is a San Francisco incorporation, and the mine lies adjacent to and north of the Star mine, and will undoubtedly prove a valuable property.

COLUMBUS DISTRICT.

NORTHERN BELL.—*True Fessure*, July 24: The drift from the bottom of the winze on the 10th level has been advanced 12 ft during the week. In the 3d level the atope above the main tunnel shows an improvement. Three ft of 85-ore is in the atope, and value of the ore in the atope. Some very rich ore is being extracted from the stopes above the east drift on the 3d level. The 10th and 2d levels show no material change. The shipment of ore approximately 95 tons. Both mills are running to full capacity.

LUCKY HILL.—This winze has reached a depth of 100 ft. The bottom is in manganese ore, and the ground is of a good character in which to make progress. The south crosscut in 40 ft, and the ground is improving. The hoisting works for the mine are arriving, and their erection will be immediate. As soon as they are ready, the work of opening the mine will be pushed ahead vigorously.

TINER.—Work has been resumed on this mine, and sinking on the ledge is progressing fairly. The croppings of this mine assay well, going from \$80 to \$180.

ENTERPRISE & NEXUS.—This tunnel has been advanced 45 ft since the contractors have begun operations. The character of the ground is improving.

WINDSOR.—The shaft is now down 95 ft, and is in a very fair character of ore. Work is being pushed as fast as possible.

GENERAL JACKSON.—The incline, which is now down 165 ft, is in small stringers of ore. Favorable progress has been made.

SINKING.—Sinking the winze still continues. It is in good ore all the way. The still is from 6 to 7 ft. The main tunnel is still progressing with good headway. It is daily expected that ore will be found.

EUREKA DISTRICT.

RICHMOND CON.—*London Mining Journal*, July 3: The usual telegram from the mines at Eureka states that the week's run was \$70,000, from 1,125 tons of ore. During the week the refinery produced ore bars to the value of \$55,000. The manager reports that a rise has been started in back of the 200 level north, near the cave he spoke of in his last; it was up 11 ft on a seam of good ore. The 400 level north of the 200 level has been advanced 27 ft in favorable ground. In the winze below the 700 level they have begun to stoop the ore; the vein is from 3 to 5 ft wide of good quality ore.

RUBY DUNDERBERG.—The force at the mine has been increased, and the output has thus been increased to 219 tons of high-grade ore. The ore smelted during the week realized about \$7,000, and as the monthly expenses average \$5,000, there is a reasonable profit. The mine has been received which it is believed will be continued monthly. The mines in the vicinity of the Ruby and Richmond are attracting considerable attention, and profitable developments are being made in several of them.

NOTES.—*Sentinel*, July 21: Mr. Joseph Mendes yesterday paid a visit to his California mine. He informs us that the property is looking exceedingly well. A new ore body has been discovered in the main shaft, which gives promise of being a great bonanza. The ore is richer than any hitherto found in the mine.

PARADISE DISTRICT.

BULLION.—*Reporter*, July 21: On Tuesday last a strike of ruby ore was made in the Bullion, at the foot of the winze. The extent of the ore body can as yet only be surmised, but the strike is a very important one, as it proves the existence of very rich ore below the 200 level, the lowest yet attained in the mine.

PARADISE.—From authentic reports we learn that the Paradise never looked better in its history. There is an abundance of ore in sight in the mine, and considerable at the mill. The working force on the claim has been increased to 40 men, and the work of extracting ore and developing the mine is being actively and very ably prosecuted.

NOTES.—It is currently reported that a company of Chicago capitalists are making overtures for the purchase of the Mount Rose. The Mary Wilder is sorting ore for shipment to the Bullion mill. J. Fitzgerald has secured a very favorable lease on the Glory, and work will be resumed without delay.

PHILADELPHIA DISTRICT.

BELMONT.—Superintendent's Letter, July 15: All work at the mine was continued without interruption during the past week, with results of the most favorable kind. We commenced on the 6th inst. the extraction of ore from the north part of the mine, and from present indications, the same can be kept up for, say, 6 months, as we have the openings about all completed, and will have but little dead work to do in this part of the mine for some time. We have discontinued driving the drifts north and south from the long raise in the north part of the mine and commenced stooping out the ore, which is looking fine.

BARCELONA.—Superintendent's Letter, July 15: Since last report of July 3th, we have advanced 6 ft in the north level, which is yielding the finest ore ever taken from the mine at any time. We are working 1 shift in the level, and average 2 tons of ore per day. One ton, first class, assays over \$500; second class, \$125 per ton. It shows a splendid face of ore over 4 ft. Upraise in fine body of ore; work is progressing finely. Have advanced 18 ft in air shaft on the surface, having water to contend with.

PIOCHE DISTRICT.

EL DORADO CANYON.—*Record*, July 17: The work on the mines at El Dorado canyon is still steadily kept up. Owing to the fact that the company is keeping their miners busy prospecting, and now have their mine in such shape that when the mill is ready to start up all they have to do is to extract ore, all the dead work having been done. The mill is expected to be running by the 1st of Oct.

SPRING VALLEY DISTRICT.

A LEDGE DISCOVERED.—*Silver State*, July 22: We learn that a large ledge has been discovered on the mountain, above the Eagle mine, in Spring Valley. We are informed that it is 15 ft wide, and that it contains very rich gold-bearing quartz. It has been named the Nugget. Specimens of the ore assay from \$300 to \$5,000 in gold to the

ton. In early days a large quartz boulder, which was studded with gold, was found under where the ledge has been discovered. The boulder created considerable excitement among prospectors, who spent weeks looking for the ledge from which it was supposed to have broken off, but their labors were in vain. The impression now prevails that the Nugget is the ledge of which they were in search, and that it will prove to be a very valuable mine.

NOTE.—A contract to sink 100 ft on the Eagle mine, owned by the Vandewater company, a new corporation, has been let. The papers have been drawn up, and as soon as they are signed by the Superintendent of the company the contractor will commence sinking.

TUSCARORA DISTRICT.

MINING NOTES.—*Eureka Sentinel*, July 20: We learn that the mines in this district are generally looking better than they have for some time past, and there is noticeable a more cheerful feeling among the business men than has been seen since last winter.

MILL NOTES.—By the 1st of August, we are assured, that all of the mills in the camp will be supplied with ore as follows: The Independence-Navy mine, with 100 tons; the Lancaster mill with Argenta ore, the Grand Prize 20-stamp mill, 10 stamps with ore from the Grand Prize mine, and 10 with North Bells Isle ore. The De Fries mill will be employed to run Belle Isle tailings.

WHITE PINE DISTRICT.

TRENCH CO.—*Eureka Sentinel*, July 22: Quite a force of men is now at work on the mines of this company. A contract has been let the past week on the shaft of the Trench mine, while work is being rapidly pushed in the drift. At this stage of development everything looks encouraging. The mine is under able management, and the wonderful richness of the ore is such that even a small chamber makes quite a bonanza.

HADEKE STATE.—A contract has been let on this mine, where an incline is to be sunk 150 ft on the hanging wall of the vein. A crosscut is then to be run back to the footwall to determine the width of the ledge, which is undoubtedly the largest in this part of the State. Recent assays from a point about 40 ft from the surface show a great improvement in this quality of the ore as depth is attained.

RECONITOR.—Men are soon to be put to work on this mine, which also displays a fair vein of quartz ore.

CON. TREASURER.—*News*, July 22: The shaft of this mine is now down 50 ft, and is in favorable ground. WARD BECHER.—The Ward Becher folks have reduced their working force, though, we learn, that the prospects in this mine are most excellent; in fact, good enough to encourage any company.

ARIZONA.

TOMBSTONE DISTRICT.—*Nugget*, July 15: The recent strikes in 2 of our mines, the Empires and Contentment, are a cause of congratulation to all the residents of the district. The strike in the Empires was made at the depth of 213 ft, disclosing an ore body of unknown width which assays from \$200 to \$300. In the Contentment, at a depth of about 300 ft, a fine body of ore was encountered. Of its extent and richness we have not heard, but understand it is all that the owners of the property could hope for. This mine lies northwest of the Empiro, and it is quite probable that the ore body encountered is a continuation of that reached in the latter. In addition to these 2 strikes, we hear it rumored that in 1 of the prominent mines on the hill, the ore is rapidly gaining in richness, and the owners are giving promise of going to gold.

MOUNTAIN MOUNTAINS.—We are assured that Gen. Ben Butler is extensively interested in mining property in the Mule mountains. His recent visit to the Pacific coast was undertaken with the intention of visiting this section, but business interests recalled him to Massachusetts. Col. Strong, of Washington, D. C., is interested with him and left here during the present week for the East, to make arrangements for the development of the property, and the erection of reduction works. It is the purpose of the company to commence operations there within the next month or 6 weeks. Gold is said to be the predominant ore in their mines, so far as developed.

GLOBE DISTRICT.—*Silver Belt*, July 17: The winze, at a depth of 150 ft from the surface, in the Mack Morris, is yielding as rich ore as when the bonanza was struck. The 240 ft level, is widening and giving \$300-ore. The drift on the vein from the winze shows the same character of rich ore. The discovery is remarkable and indicates permanence.

STONEWALL NO. 1.—Geo. H. Cook, who, the present week, visited the Chamberlin, or Stonewall No. 1, brings favorable reports in regard to it. He thinks it 1 of the mines of the district. The new shaft is down 50 ft and all in ore.

OREGON.

JACKSON COUNTY NOTES.—*Democratic Times*, July 23: Barkdell & Kline struck another rich pocket of quartz in their mine at Blackwell the other day. The rock pays well, \$18 in gold having been obtained from about 500 lbs crushed in their arastra. The ore was obtained from the same ledge discovered by them last winter, but some distance from the original place of discovery. They have been prospecting other ledges in the vicinity, some of which will pay for milling. Work has been commenced on the main ledge and it is proposed to keep the arastra busy.

ROOPE RIVER MINES.—Savage Bros., who have been plying near the banks of Rogue river during the last season, have suspended operations for the present. They have cleaned up about one-third of the ground washed off and secured good wages for their work.

WILLOW SPRINGS.—Egan, Schump & Co. have ordered a pump for their quartz mine near Willow Springs, which will enable them to keep the water out of the shaft. Drifting is being continued, with good prospects, some excellent rock having been taken out this week. The pulverized ore is being worked by rocker and yield well. The company will probably start their arastra soon again. Roten & Co. have their arastra in the Willow Springs district in operation and are crushing fair rock.

ITEMS.—The Sterling Co. will not clean up until the end of the season. The Squaw Lake Co. have reset their pile and are busily plying again. N. Schaefer & A. Trunk are now engaged in cleaning up the Falling claim on Jackson.

BAKER COUNTY.—*Bedrock Democrat*, July 21: There has been another rich discovery in quartz within the past few days, near Sutton creek, about 12 miles from this city. The discoverer has a 4-foot ledge, from which they have already taken out some fine specimens. We saw the first piece that was taken from the croppings, and it is the richest and coarsest quartz gold we have yet seen.

Origin and Classification of Ore Deposits.—No. 3.

[By PROF. NEWBERRY, in the *School of Mines Quarterly* for March.]

Superficial Deposits.

These include the accumulations of gold, stream-tin, platinum, gems, etc., which are obtained from the surface material, gravel, sand and clay, derived from the mechanical decomposition of rock masses through which metals or ores were sparsely distributed. Thus, gold usually occurs in small quantity in the quartz-veins of metamorphic rocks. By the erosion of these rocks, having been freed from its matrix, and that more or less perfectly removed, this gold is concentrated by a natural washing process similar to that employed by man, but on a grander scale. In the same manner, the oxide of tin, which is hard, heavy and very resistant to chemical agents, is distributed sparsely through granitic rocks or vein-stones; and where these have been eroded, the cassiterite remains in the alluvial deposits of streams, where it can be cheaply and easily collected.

Superficial deposits have probably furnished nine-tenths of all the gold that has been obtained by man, the greater part of the tin, all the platinum and its associated metals (iridium, osmium, etc.), and all the gems except the emerald, which in South America is obtained by mining. Thus, it will be seen that the surface deposits are scarcely less important, economically, than the others. The superficial deposits of gold are for the most part confined to the foothills or mountain ranges, and are the products of the erosion effected by ages of frost, sun, rain and ice, which are continually wearing down all the more elevated portions of the earth's surface. Shore-waves also, in some instances, have worn away the rocks against which they have beaten, and have produced accumulations of debris that contain gold, platinum, gems, etc., in sufficient quantity to be economically worked. When a beach deposit of this kind has been raised above the sea-level, it sometimes becomes convenient and profitable mining ground. On the coast of Oregon, at and above Port Orford, the beaches now yield gold, iridium, and osmium in sufficient quantity to afford profitable employment to quite a mining population; and in the Black Hills, the old Potsdam sandstone beach, formed by the beating of the Silurian sea upon cliffs of Laurentian and Huronian rocks traversed by auriferous quartz-veins, now constitutes what is there known as the "cement deposits," from which a considerable portion of the gold in this region is obtained. As has been mentioned, however, the chief supply of gold in all ages has come from the debris that have accumulated at the foot of mountain slopes. All mountain chains are composed of metamorphic rocks, and nearly all the mountain ranges of the globe are traversed by quartz-veins, in which are concentrated much of the gold that was originally finely disseminated through the sedimentary strata—conglomerates, sandstones, shales, etc.—now granites, schists, and slates.

By the lateral pressure that has metamorphosed the sedimentary rocks, and produced the segregation of the quartz-veins, great folds and ridges were formed, which, rising high above the general surface, act as condensers of moisture, and receive the most copious precipitation from the clouds. Hence on these mountain sides an enormous system of water-power is developed, which is spent in grinding up the rocks and transporting the debris to the bottom of the slope. Here it is further washed, sorted, and the gold locally concentrated to form the rich "placer" diggings. As no great skill or expensive mining machinery is required to work placer deposits, every man with good health, a pick, shovel, pan and stock of provisions may go into the business. Gold washing is the simplest, as it was probably the earliest, of all mining enterprises, and has at different times employed nearly the entire population of a district or country. It is not surprising, therefore, that it has resulted in the production of an enormous quantity of gold. It is evident, however, that most of the placers of the world have been already exhausted, and while the little-known continent of Africa promises to furnish a large amount of the precious metal from its "golden sands," we can hardly expect that the production of California, Australia and New Zealand will even be repeated in the world's history.

Unstratified Deposits.

These have been divided into: 1. *Eruptive masses*; 2. *Desseminated through eruptive rocks*; 3. *Contact deposits*; 4. *Stockworks*; 5. *Fallbands*; 6. *Impregnations*; 7. *Chambers*; 8. *Mineral veins*.

Of eruptive masses of metalliferous matter I must confess myself incredulous. Examples of these are cited in the crystalline iron ores of the island of Elba, those of Nijni, Tagilsk in Russia, and in Sweden, and even the iron ore-beds of Lake Superior and Missouri. As late as 1854, this was the view taken of our crystalline iron ores by Whitney in his *Metallic Wealth*; but great advances have since been made in our knowledge of these deposits, and it is now generally conceded that all our crystalline iron ores are simply metamorphosed sedimentary beds. The evidence is accumulating that those of the old world have the same character. Prof. Otto Torell, the Director of the Geological Survey of Sweden, recently told me that he had visited all but one of the iron districts of Sweden, had found in all these the iron ores were metamorphic, and he had no doubt that

those yet unexamined were of similar nature. Where metamorphic action has been peculiarly violent, the beds of iron ore have been more or less dismembered, and perhaps in some instances have been actually fused; but that any bed of iron ore is the result of an eruption from the interior of the earth, is scarcely to be credited.

The examples of the occurrence of metalliferous matter disseminated through eruptive rocks are by no means uncommon, and the amygdaloid traps of Lake Superior, in which the cavities formed by gases have been more or less perfectly filled with copper, suggest themselves at once. Pyrites, magnetic iron and platinum are found sparsely diffused through trap-rocks, and are sometimes concentrated in such a way as to form valuable deposits when the trap decomposes.

Contact deposits are usually understood to be accumulations of metal or ores along the planes of contact between two strata; and the sheets and strings of copper which are concentrated at the junction of the trap and sandstone in some parts of the south shore of Lake Superior constitute illustrative examples of this class of mineral deposits. There is, however, considerable diversity in character among the deposits grouped under this head; the chief distinction being that in some cases the ore or metal has been segregated from one or the other of the strata at the time of their deposition, and in others it has come from a foreign source, and has been deposited in a more or less continuous sheet in cavities formed between the surfaces of the adjacent rock-beds. To the second of these classes would seem to belong the argentiferous ores of Leadville, Col. These are deposited along the plane of junction between an underlying limestone and overlying porphyry, and undoubtedly accumulated in vacant spaces formed by the solution of the limestone. These ore bodies have apparently much in common with the pockets and chambers excavated in certain limestone beds, and subsequently filled with ore, to be described farther on. The true structure of these Leadville ore bodies can, however, only be accurately learned when they shall be penetrated below the zone of unchanged sulphurets into which they will undoubtedly merge in depth.

The term *stockwork* is applied in the old world to a mass of rock or veinstone penetrated in all directions by small intersecting sheets or veins in such a way that the whole mass is mined out. Some examples of this kind of deposit may be found in most of our mining districts; but the most important which have come under my observation are in the Quirrh mountains, in Utah, and at Silver Cliff, Col. In the first of these localities, beds of quartzite—in the second, of porphyry, have been shattered, and the crevices between the fragments have been filled with ore deposited from solution.

The name *Fallband*, or rotten layer, originated in the silver mines of Kongsberg, in Norway, where there are parallel beds of rock impregnated with the sulphides of iron, copper, zinc, etc., which, by their decomposition, have rendered these beds so soft as easily to be removed. We occasionally meet with pyritous rock in this country, which decomposes in the same way, but none yet known to me has any considerable importance as a metalliferous deposit.

Impregnations may be defined to be saturations of porous rock with a mineral solution or vapor from which ore has been deposited. The cinnabar which is sometimes found impregnating unchanged or metamorphosed sandstone is generally cited as affording typical examples of impregnations. In such cases, which occur in California and South America, the deposit of ore has been ascribed by some writers to vapors, by other to solution, and it would seem that the latter is the more creditable theory, although the vaporization of mercury is easily effected, and, like other metals, it may be transported by steam, as we have proof at the geysers in California. More familiar and satisfactory exhibitions of impregnation are, however, afforded by the copper-bearing sandstones of Lake Superior, New Jersey, and New Mexico, and the silver-bearing sandstones of Silver Reef, in southern Utah. In all these cases, it is evident that a porous rock was once saturated with metalliferous solution, from which in the Lake Superior region, metallic copper was precipitated; in New Jersey and Mexico, sulphides of copper and iron; at Silver Reef, sulphide of silver. As such repositories of the metals are easily penetrated by surface water and air, we usually find the sulphides decomposed to a considerable depth; the copper ores converted into carbonate and silicate, the sulphide of silver into the chloride.

WAGES OF FARM LABORERS.—The annual report of Col. Wortington, Statistician of the Agricultural Department, just made public, gives some interesting facts concerning farm labor and wages. In the Pacific and mining States and Territories the range of wages for farm laborers, without board, is between \$30.75 in Montana and \$22.50 in Washington Territory. Of the States east of the Missouri, Minnesota pays her farm laborers better than any Northern State, the monthly wages, with board, being \$16.75, while Vermont pays only \$12.60. In the Southern States prices paid range from \$12.26 in Louisiana to \$7.32 in South Carolina, the average being \$9.60. The cost of keeping a laborer for the average of the whole country in 1880 is \$7.17 per month against \$7.25 in 1879. The demand for laborers is good in all sections of the country.

The Bottom of the Sea.

The coast survey steamer *Blake*, commander, J. R. Bartlett, U. S. Navy, recently returned from a cruise taking soundings, serial temperatures, etc., in the course of the Gulf stream, under instructions from C. P. Patterson, superintendent of the Coast and Geodetic Survey, has brought some very interesting data in regard to the depths of the western portion of the Caribbean sea. The depths and temperatures obtained last year in the Windward passage, between Cuba and St. Domingo, were verified, and a few hauls of the dredge taken directly on the ridge in this passage. The data obtained render it very probable that a large proportion of the supply for the Gulf stream passes through this passage, and that the current extends in it to the depth of 800 fathoms. A few lines of soundings with serial temperatures were run from Jamaica to Honduras bank via Pedro and Rosalind banks, and it was found that the temperature of 39½ degrees, obtained at all depths below 700 fathoms in the Gulf of Mexico and western Caribbean, could not enter through this portion of the sea. But the temperature at the depth of 800 fathoms on the ridge in the Windward passage, between Cuba and Hayti, was found to agree with the normal temperature of the Caribbean and the Gulf of Mexico, viz., 39½°. Soundings were taken between Hayti and Jamaica, developing a general depth between these islands not exceeding 800 fathoms, except when broken by a remarkably deep channel connecting the waters of the main Caribbean south of St. Domingo with those north of Jamaica. This channel runs close to Hayti with a greatest depth of 1,200 fathoms, and a general depth of 1,000 fathoms. Its course is northerly along the western end of Hayti, where it does not exceed a width of five or six miles; thence westwardly, south of Navassa island, with a tongue to the northward between Navassa and Formigas bank, and another to the westward between Formigas bank and Jamaica.

A line of soundings was run from St. Jago de Cuba to the east end of Jamaica, where a depth of 3,000 fathoms was found 25 miles south of Cuba. This deep place was found by subsequent soundings to be the eastern end of an immense deep valley extending from between Cuba and Jamaica to the westward, south to the Cayman islands, well up into the Bay of Honduras. The Cayman islands and the Misteriosa bank were found to be summits of mountains belonging to a submarine extension (exceedingly steep on its southern slope) of the range running along the southeastern side of Cuba. The deep valley is quite narrow at its eastern end, but widens between the western end of Jamaica and Cape Cruz, where the soundings were 3,000 fathoms within 15 miles of Cuba, and 2,800 fathoms within 25 miles of Jamaica. Near Grand Cayman the valley narrows again, but within 20 miles of this island a depth was found of 3,428 fathoms. The deep water was carried as far as a line between Misteriosa bank and Swan islands, with 3,010 fathoms within 15 miles of the latter. On a line between Misteriosa bank and Bonacca island there was a general depth of 2,700 fathoms, and a depth of over 2,000 fathoms extended well into the Gulf of Honduras. Between Misteriosa bank and Chinchorra bank the soundings were regular at 2,500 fathoms. North of Misteriosa and Grand Cayman to the Isle of Pines and Cape St. Antonio the soundings were generally 2,500 fathoms. The serial temperatures agree, in relation to depth, with those obtained in the Gulf of Mexico by Lieutenant-Commander Sigbee, and in the eastern Caribbean by Commander Bartlett; decreasing from the surface to 39½° at 700 fathoms, or less, and constant at that temperature for all depths below 700 fathoms. At depths greater than 600 or 700 fathoms, the bottom was always found to be calcareous ooze, composed of pteropod shells, with small particles of coral. These pteropod shells, as noticed in previous expeditions by different nations, appear to be an important factor in the determination of the movement of great bodies of sea water. The ridge at the Windward passage is bare coral rock, and on the south side the pteropod shells were found to be much more numerous than to the northward of the ridge.

Soundings and serial temperatures being the special objects of the cruise, dredgings were only incidentally attempted, for the purpose of reconnoitering, as it were, the ground, and it was found that the area passed over was not nearly so rich in animal life as that in which dredgings were made last year under the lee of the Windward islands at the eastward of the Caribbean sea.

The development of the extraordinary submarine valley in the western Caribbean sea is a matter of great interest, considered as a physical feature. This valley extends in length 700 statute miles from between Jamaica and Cuba, nearly to the head of the Bay of Honduras, with an average breadth of 80 miles. Curving around between Misteriosa bank and Yucatan, and running along between Cuba and the ridge of the Caymans for a distance of 430 miles, with a breadth of 105 miles, it covers an area of over 85,000 square miles, having a depth nowhere less than 2,000 fathoms, except at two or three points (the summits of submarine mountains), and with the greatest depth, 20 miles south of the Grand Cayman, of 3,428 fathoms, thus making the low island of Grand Cayman, scarcely 20 ft. above the sea, the summit of a mountain 20,568 ft. above the bottom of the

submarine valley beside it, an altitude exceeding that of any mountain on the North American continent above the level of the sea, and giving an altitude of the highest summit of Blue mountain, in Jamaica, above the bottom of the same valley, of nearly 29,000 ft., an altitude as great probably as that of the loftiest summit of the Himalayas above the level of the sea.

For the despatch portion of this great submarine valley the Superintendent of the Coast and Geodetic Survey has adopted the name of "Bartlett Deep."—*Iron Age*.

What is Water Gas?

The popular idea of water gas is that it consists of oxygen and hydrogen, and is formed by the decomposition of water. What it is, Dr. Wahl thus very clearly explains:

"Water gas may be defined to be the gaseous product resulting from the inter-action of steam and carbon at a high temperature. Generally speaking, the mode of its manufacture is to pass steam through a thick layer of glowing coal. The result of this procedure will be very easily understood by reference to the following explanation: The glowing coal (carbon) seizes upon the oxygen of the steam, uniting with it to form carbonic acid and liberating hydrogen. The carbonic acid thus formed is, however, obliged to pass through a considerable layer of glowing coal (carbon) before it can escape, and this carbon has so strong an affinity for oxygen that it deprives the carbonic acid of one equivalent of its oxygen, reducing it to the state of a lower oxide of carbon. The product which results from these several reactions is 2 equivalents of hydrogen and 2 equivalents of carbon oxide; or, expressed in chemical language, 2H + 2CO. This product is what is known as water gas. It is incorrect to assert that any positive gain in heating effect is obtained by this process, for the energy expended in the process of decomposing the water is precisely equal to the additional heat given out by the combustion of the water gas over what would have resulted from the combustion of the carbon alone. On theoretical grounds, therefore, there can be no economy in the process; but there is a gain in practice, and this is due to the fact that the combustion of a gaseous fuel can always be effected with greater economy in our furnaces, stoves, etc., than that of a solid fuel. The gain, therefore, is to be ascribed to the physical condition of the fuel, and not to any advantage resulting from the chemical reaction that has taken place. This is a very common error that is entertained even by otherwise well-informed persons. We look upon the future of water gas as highly promising. With its aid it is made possible to produce illuminating gas more cheaply than by any other process, by simply enriching it with the vapors of petroleum, or of other substances rich in illuminating elements. But the grand field of water gas for the future will lie in filling the place of a fuel for industrial and domestic uses to take the place of coal. We think the time is not very remote when water gas will be distributed to our houses just as coal gas is now distributed—when coal and wood fires, with their abominations of dirt and ashes, will only be known as things of the past."

The unscientific, as well as the scientific, world is interested in the discussion of the relative merits of the new water-gas systems in comparison with the old coal-gas systems. The old theory, promulgated by scientific journals and those claiming to be scientific writers, was that water gas could not be produced in any form economical enough for general use. But it now appears that these gentlemen were laboring under a mistake. Several methods or systems of producing water gas have of late been introduced with marked success. These new methods are being brought into competition with the old coal-gas system, and the public will have a chance to observe the result.

Yonkers, N. Y., is to be favored with the opportunity of observing a contest between the two systems on quite an extensive scale. Not only will they have a chance to compare the old with the new, but there will be a rivalry between several of the new systems, so that they can determine, if possible, whether water gas is better than coal gas, and which of the water-gas systems is the best.

The *Engineering and Mining Journal* says in regard to the interesting contest: The Motay and Lowe systems are spoken of in the highest terms. The contest now going on in Yonkers will be productive of good, not only in showing up the relative merits of the different processes, but likewise their deficiencies, if any exist. Such close competition begets improvement, and the new methods will at the outset have the advantage of the severest tests in a practical manner. If it is demonstrated that the new gas is cheaper and better than the old, then it will not require much time to introduce the same quite generally in the principal cities of the country.—*Iron Age*.

INSECURITY OF AMERICAN BRIDGES.—Prof. George L. Vose, in the *Railroad Gazette*, says that 30 bridges, on an average, break down in the United States every year. No system of inspection or control at present existing has been able to detect in advance the defects in these structures, or to prevent the disasters. A system, practical, simple and inexpensive, can be had, which, if properly carried out, will insure in nearly all cases, if not all, the public safety. It lies with the public to say whether or not it will have such a system.

The Nicaragua Inter-oceanic Canal.

The full text of the inter-oceanic canal concession granted by Nicaragua to the American provisional society has been received at Washington. It is signed by Don Adam Neordenas, Minister of Foreign Affairs, and A. G. Menocal, a member and commissioner of the provisional society. The concession has been ratified by the Nicaraguan Senate, and published as a law by the republic. The provisional society secures the exclusive privilege to construct a ship canal across Nicaragua, the canal to be of sufficient dimensions to accommodate steamers of the largest class used between Europe and America, and the locks are to be not less than 500 feet long and 28 feet deep. The concession is for 99 years from the date of the opening of the canal for general traffic, and at the expiration of that period the Nicaraguan government is to take possession of the canal in perpetuity, with the right reserved to the company to lease it for another 99 years. During the period of concession the company is to have the privilege of constructing a railway along the whole or any part of the canal, also such telegraph lines as it deems necessary for the construction and working of the canal, and these lines shall transmit public messages free of charge. The government of Nicaragua will declare terminal ports. The canal itself throughout its length is to be neutral, and transit in case of war between other powers and Nicaragua shall be uninterrupted. In general the canal shall be open to the free navigation of all vessels, provided they pay dues and observe the regulations of the company. Troops of foreign nations and vessels of war will be allowed to pass through the canal under the regulations of the existing treaties. Vessels of war belonging to other nations engaged in hostilities with Nicaragua or any other republic of Central America will be rigorously excluded. An effort will be made to secure a guaranty from all the powers of the neutrality of the canal, of a zone along it and of a zone in the vicinity of the terminal ports where the dimensions will be defined. This concession with all its advantages and privileges will appertain to the construction company and is transferable only to a company which is to be organized by the provisional society, and in no case can it be transferred to a foreign government or power. It is to be organized in the usual manner of such enterprises, with its principal office in New York, or where it may deem most convenient. Its designation will be "The Nicaraguan Ship Canal Company." The company is to be allowed to bring immigrants to Nicaragua freely from all parts of the world, but it is required to bind itself not to interfere in questions which directly, or indirectly, may affect the public peace of Nicaragua, and not to give protection to criminals or disturbers of the peace. It is exempt from every form of taxation during the period of this concession.

A Steam Catamaran.

The steam catamaran built at Nyack, on the Hudson, by William Voorhis, was launched on the 7th inst. The two hulls are cylindrical in shape, very much resembling two immense cigars. They are constructed of 3-16-inch iron plates, are 200 ft. in length and 5 ft. 6 inches in diameter at their largest part, tapering to a sharp point fore and aft. They are 9 ft. apart, connected by means of white pine beams resting on white pine caddles. They are kned by back-mast knees and braced by iron braces on the inside and outside, thus furnishing a deck 25 ft. in width over all. All this is enclosed, making a commodious and pleasant cabin almost its entire length, with a small open-deck space outside fore and aft. The rudder-posts—one to each hull—come up through sleeves 20 ft. forward of the extreme after part of the hulls, and playing under them. The rudders themselves are 2 ft. deep and 6 ft. in length, constructed of thin iron. The rudder-post is secured to them 2 ft. abaft the forward end. They are geared together at the top, and both are worked by one wheel, the pilot-house being in the usual location, above the forward cabin. The steamer is to be propelled by a Wells balance engine of 476 horse-power, having a cylinder 24 inches long, 12 inches in diameter with a stroke of 12 inches. The shaft is of steel 4 inches in diameter, 8 ft. long, and is placed on an incline giving the boat an upward and forward movement. It is expected to make 325 revolutions a minute. The engine is supplied with steam by a Herreshoff coil boiler 8½ ft. long and 8½ ft. high, containing 1,250 ft. of coil. The propeller is six-bladed, 8 ft. in diameter, and graduated from 7½ to 8½ ft. pitch. The hub is out of water, as are also four of the six flanges. The whole boat is 42 tons burden, with a displacement of 72 tons, and it only draws 2 ft. of water. Thos. Magee, of Nyack, is the builder, and the cost of the boat is about \$15,000. Commodore Voorhis has determined to name her *Henry W. Longfellow*. He expects to run her as a ferry between Nyack and New York, and is confident she can make the run—28 miles—in one hour. *American Manufacturer.*

THE METRIC SYSTEM.—The metric system became obligatory on the 15th inst. in the kingdom of Spain and all its colonies. The Turkish government has also ordered the introduction of this system into all its provinces, including Tripoli and Arabia. The cubit gives way to the meter in Jerusalem, and the shekel to the kilogram.

USEFUL INFORMATION.

LIQUID GLUE.—You cannot use mucilage as glue, because it is not gln and does not possess the sticking qualities of good glue. It is made of starch, dextrine or gum arabic, with some acetic acid, or some equally preservative substance in it to make it stick on tin cans or on metal. You must mix a few drops of nitric acid with the mucilage just before you are about to use it, otherwise it will come off. This acid acts on the metal and destroys the polish, which prevents the sticking. It is the same with varnished objects. In order to make labels stick where they have a tendency to come off, mix a little alcohol with the mucilage. This partially dissolves some of the varnish, takes the gloss away under the label and causes adhesion. Or you can rub the varnish with a little alcohol at the place where the label is to be put on; or you may stick the label on with varnish instead of mucilage. Some kinds of varnishes are good for this purpose, others not. In order to make a better sticking mucilage, you must not use starch or gum at all, but the best quality of glue. Soak it over night in plenty of water; in the morning pour the excess of water off and put on a gentle fire, so as to melt the glue in the water it has absorbed during the night; but thin it with strong vinegar, or with acetic acid, when you want it thick, and you will have mucilage with which you can glue wood together, but you must not expect that it will be as strong as if you had used hot gln, as cabinet-makers always do.

EDGE-LAID BELTS.—According to Leigh, a better method of producing a broad belt than the usual American double leather belting sewed together—a method by which the article can be made with the greatest ease, of any thickness or width, perfectly equal in texture throughout, and alike on both sides—consists in cutting up the hide into strips the width of the intended thickness of the belt, and setting them on edge, these strips to have holes punched in them about one-eighth of an inch in diameter and one inch apart; nails, made of round wire, clinched up at one end for a head and flattened at the other, are used for fastening the leather strips together. Each nail is in this case half the width of the intended belt, and after the strips are all built upon the nails, the ends of the latter are turned down and driven into the leather, thus making a firm strap without any kind of cement, splices, or similar treatment. When a strap made in accordance with this plan requires to be tightened, it is only necessary to take it asunder at the step lines of the splice, cut off from each end of the strap what is required, and piece up again with wire nails or laces, going entirely through the strap.

LEATHER FROM SHEEP'S STOMACHS.—An American inventor has devised a new mode of utilizing a waste material of which a plentiful supply exists everywhere, but of which Australia produces perhaps a larger proportion than any other country. He has succeeded in making a very good, light, fine leather from sheep's stomachs, or rather from the middle membranes of the stomach. The mode of preparation, according to *India and the Colonies*, is to carefully remove both the inner and outer coatings, when a thin, white, skin-like material is produced, which is subjected to a mild process of tanning by means of a mixture of alum, glycerine and yolk of eggs mixed with flour into a paste. The paste is spread over the material and allowed to remain for about a day, when it is removed and a small quantity of linseed oil rubbed into the resultant "leather."

TO MAKE COURT PLASTER.—Soak isinglass in a little warm water for 74 hours; then evaporate nearly all the water by gentle heat; dissolve the residue in a little dilute alcohol, and strain the whole through a piece of open linen. The strained mass should be a stiff jelly when cold. Now stretch a piece of silk or sarson on a wooden frame, and fix it tight with tacks or pack thread. Melt the jelly and apply it to the silk thinly and evenly with a badger-hair brush. A second coating must be applied when the first has dried. When both are dry, apply over the whole surface two or three coatings of balsam of Peru. Plaster thus made is very pliable, and never breaks.

IMPURE WATER IN LOCOMOTIVES.—Some of the difficulties encountered in the use of impure water in locomotives in some of the Western States may be formed from the following letter from a Western mechanic: "At the end of the road we have so much alkali water to contend with that we are obliged to change the flues every six months. Besides this, we have to wash our engines thoroughly for every 400 miles run, with a force pump and 70 lbs. of pressure, and even with all this constant cleaning the flues will not last longer than six months without giving much trouble from leaking on account of the mud and scale."

DRAWING PAPER of any thickness may be made perfectly transparent, so that it may be used for tracing, by dampening with benzine. As the benzine evaporates the paper again becomes opaque. The tracing may be done with India ink or water colors.

WITHERED LEAVES having the yellow, brown or red autumnal colors can be made green again by steeping them in water with a little zinc powder.

FIREPROOF PAPER.—To make a fire and water-proof paper, *Les Mondes* says: Mix one-third of ground asbestos fiber with two-thirds of paper paste in a solution of common salt and alum. Pass the mixture into a machine, plunge the paper thus made into a bath of dissolved gum lac and send it through the finishing rolls, when it may be cut into sheets. The salt and alum increase the strength of the paper and its resistance to the action of fire. The lac renders it impermeable to moisture, without interfering with its fitness for the reception of ink.

TO WELD HORN OR TORTOISE SHELL.—The worker should be supplied with pincers or tongs of different sizes and forms, so that when applied to the joints to be made, the tool will reach three or four inches beyond the joint. The edges to be joined are filed to a bevel or lap-joint, care being taken to have them quite clean and free from grease. The edges are joined after being wet with water, the pincers applied hot, and followed with water. By this procedure, the shell will be found to be joined as if it was one piece.

A COMPANY, lately organized in Baltimore, is engaged in exporting baled manure. Use is made of half a dozen such presses as are employed in compacting cotton. The manure is made up into parcels resembling bales of hay, and when the parcels are covered with burlap bagging they look as well as do packages of dry goods. The manure is shipped to North Carolina, Virginia and other States, and to Cuba.

REMOVING HARD PUTTY.—Hard putty, it is said, can be removed from a window-sash with great readiness by simply applying a piece of heated metal, such as a soldering iron or other similar instrument. When heated—but not red-hot—the iron is to be passed slowly over the putty, which is thereby rendered so soft as to be easily parted from the wood.

CEMENT FOR IRON AND STONE.—A mixture of litharge and glycerine hardens rapidly, and is said to make an excellent and durable cement for iron or stone work. It is not affected by exposure.

TO TAKE MARKING INK OUT OF LINEN.—A saturated solution of cyanuret of potassium, applied with a camel's-hair brush. After the marking ink disappears, the linen should be well washed in cold water.

A DELICATE INSTRUMENT.—One of the most delicate instruments known to science is Edison's tasimeter, or heat measure. The rapid passage of the hand before it at a distance of 34 feet causes a deflection of the needle of 20°.

GOOD HEALTH.

New Method of Prolonging Life.

We have had several letters about a book entitled "Makrobistic and Eubank," a scientific method of prolonging human life. We have not yet been able to procure a copy of the work. It is to be had only in the German language. It is not to be found in our book-stores; but a London paper has reviewed it and states that one of the secrets promulgated in this remarkable work is that long life will be reached by continually increasing the use of lemons. After arriving at 40 years of age, the prescription is two lemons per day for a lady, and three for a gentleman, increasing the dose every ten years as long as the person lives. It is said that the author got his idea from the fact that Count Waldeck reached the age of 120 years, and that for years he had eaten a large amount of horse-radish soaked in lemon juice as an antidote to the sluggishness of his liver. It would take more than one experiment to prove the truth of this remarkable history; still there is no doubt that the use of lemon juice may be very beneficial for those who are advancing in age, providing it does not disagree with the stomach. It would certainly have a tendency to thin the blood to some extent, and this would render it easy for the heart, which grows feeble as age advances, to circulate it. Other means of prolonging life might be equally beneficial. As a rule, the older one grows the less fruit he eats, partly from the fact that the teeth become imperfect, and it is difficult to masticate them; but it is evident to us that fruit in proper quantities may be used to great advantage by well persons as well as sick ones. —*Herald of Health.*

[The lemon should be used much more freely than it is. It is recommended by medical men everywhere; and if the treatise of this German professor of medicine, for such he is, will only render its use more general, it will accomplish a good work. The time is fast coming when, by more general cultivation, the lemon and lime will be offered so cheap that they may be freely used in every household. California and Florida will eventually supply the entire country with the choicest of all the citrine fruits.]

Does Eucalyptus Prevent Fever.

In the last number of *Nature* some very positive statements are made as to the value of the eucalyptus or blue gum tree of Tasmania in destroying fevers in malarial districts. The testimony in support of this power, it says, is most convincing. In malarial districts near eucalyptus forests fever seems to be unknown, and in parts of Corsica and Algeria, where the tree has been planted for the sake of its reputed virtues, endemic fevers have been stamped out. M. Gimbert, in a report to the French Academy, instanced the case of a farm situated in a pestilential district about 20 miles from Algiers, where by planting a number of trees the character of the atmosphere was entirely changed. Similar testimony comes from Holland, the south of France, Italy, California and many other parts of the world as to the febrifugal attributes of this tree.

In no case is the evidence more convincing than in that of Algeria, as related by Dr. Santra, and quite recently, by Consul Playfair. Large tracts of land have been transformed by the agency of the "fever-destroying tree," as it has come to be called, and wherever it is cultivated fevers are found to decrease in frequency and intensity. Fewer districts in Europe have a more evil reputation than the Campagna as a veritable hot-bed of pestilential fever, and the people who know the country around Rome may remember the monastery at Tre Fontane, on the spot, as the tradition tells, that St. Paul met his death. Life in this monastery meant death to the monks, but since the eucalyptus has been planted in the cloisters fever has disappeared and the place has become habitable.

INFECTION FROM MOSQUITOES.—The discovery that mosquitoes carry filaria in their probosces, and infect the human subject with that much dreaded worm parasite, has attracted considerable attention among the English Microscopists. The matter has been brought before the Quekett Microscopical Club, by Dr. Cobbold, the President, who is one of the highest authorities on this subject. Particulars of various cases were given in which it was proved that those suffering from filaria had received the contagion from mosquitoes, and mosquitoes themselves infected with filaria were shown. Filaria are very minute worm-like parasites, which on entering the human body, breed until they increase to countless numbers. By recent advices we learn they have the power of entering and leaving the blood at pleasure; they usually invade the circulation about seven o'clock in the evening, and increase until about midnight, after which time they retire to other parts of the system.

CROSSNESS AND IRRITABILITY.—Much of the crossness, irritability and general unamiableness which characterize certain children and make their presence so annoying springs from neglect of their happiness in some direction. Either from indiscreet indulgence, undue severity, or careless negligence, their physical system is out of order, or their temper is soured, and, feeling uncomfortable, they naturally vent their discomfort upon others. In describing a young child the words "good" and "bappy" are almost synonymous, and no effort to make him the former can be successful as long as the latter is neglected.

IMPORTANCE OF SOUND REST.—Nothing gives more mental and bodily vigor than sound rest when properly obtained. Sleep is our great replenisher, and if we neglect to take it regularly in childhood, the result will be all the worse for us when we grow up. If we go to bed early, we ripen; if we sit up late, we decay; and sooner or later we contract a disease called insomnia, or sleeplessness, allowing it to become permanently fixed upon us, and then we begin to decay, even in youth. Late hours are shadows from the grave.

AFTER THE PHYSICIANS.—The New York Legislature has passed a law requiring the registration of all practising physicians. This law also compels a practitioner of medicines coming from another State to prove his standing before the faculty of a New York medical college. Physicians in good standing do not complain of this law. In fact, they did a good deal to get it passed, as a protection to the profession against empiricism. Human life is too valuable to be trifled with, and no means can be too rigid which are devised for its protection. In this view, the New York law will meet with general approval.

DRINKING BLOOD.—It is said that between 200 and 300 men and women of St. Louis drink daily from a half to a pint of blood piping hot from the veins of slaughtered cattle. More blood drinking by consumptives and aged persons is done in September and October than during the remainder of the year. The blood of young steers is the best, and should be caught as it comes from the animal, and should be drunk while the foam is still on and the steam rising. Consumptives are advised, in addition to drinking the blood, to sit in a slaughter-house for a couple of hours each day at killing time to imbale the "steam" of the running blood.

BEEFSTEAK chopped up fine and baked with flour and yeast in the form of a "meat-bread" loaf is the latest dietetic sensation. It is asserted that meat thus treated entirely disappears during the process of purification, the nutritive principles becoming incorporated with the bread.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Wanted—An Ohe-
lisk; Lively Times in Calaveras County; Milk Under the
Microscope, 65. The Week; The Condition of the
Comstock, 72. Union Consolidated Yield; Hope for
the Castaways, 73. Notices of Recent Patents, 76.
ILLUSTRATIONS.—Pure and Diseased Milk as Seen
with the Microscope, 65. Map of Mineral King Dis-
trict, Tulare County, 72. View in Mineral King Dis-
trict, 73.
CORRESPONDENCE.—Mining Around Reno, Ne-
vada; Notes from Arizona, 66. Mineral King District,
Tulare County, 72-73. Letters from the Comstock—
No. 5, 73.
MISCELLANEOUS.—California Chrome Iron Ores;
The Quinn Mine; High Mines; A Siam Sapphires Mine;
Fossil Shark's Teeth, 63. Origin and Classification of
Ore Deposits—No. 3; The Bottom of the Sea; What is
Water Gas? 70. The Nicaragua Inter-oceanic Canal;
A Steam Catamaran, 71. Entry of Public Lands;
Compressed Air Locomotive; Scientific Lumbering; The
Saddle Against the Buggy, 74.
MECHANICAL PROGRESS.—Tempering in Sand
and Tempering Chisels; Use of Glass for Construction;
Malleable Nickel; Hints Concerning Saws; Ancient and
Modern Mortars, 67.
SCIENTIFIC PROGRESS.—Quantitative Analysis
by the Spectroscope; Wind Pressure; Electrical Insects;
Premium of \$1,000 for Scientists; The Practical Value
of Science, 67.
MINING STOCK MARKET.—Sales at the San
Francisco, California and Pacific Stock Boards, Notices
of Assessments, Meetings and Dividends, 68.
MINING SUMMARY from the various counties of
California, Nevada, Arizona and Oregon, 68-69.
USEFUL INFORMATION.—Liquid Glue; Edge-
Laid Belts; Leather from Sheep's Stomachs; To Make
Court Plaster; Impure Water in Locomotives, 71.
GOOD HEALTH.—New Method of Prolonging Life;

The Week.

Since our last issue the city has been visited
by two distinguished members of President
Hayes' cabinet—Mr. Carl Schurz, Secretary of
the Interior, and Mr. R. W. Thompson, Secre-
tary of the Navy. Apart from the desire for
relaxation and recreation, and the demands of
politics, we presume the visit of these gentle-
men has reference to the business of their de-
partments; and it is to be hoped that both of
them will gather knowledge which will be of
service to the country at large and to Califor-
nia in particular. They are entitled to the
kindest consideration.

A memorable incident has occurred in the
city during the week. On Wednesday, Sir
Thomas Hasketh, an English gentleman on a
tour of pleasure, on learning of the probable
condition of the crew of the foundered ship
Mathilde on the island of Socorro, almost at a
moment's notice dispatched his steam yacht to
the succor and rescue of the unfortunate cast-
aways. It was the graceful act of a humane
English gentleman, and will enlist the admi-
ration and love of men and women wherever
the noble deed is known.

The return of the census shows that the pop-
ulation of California, like that of every other
State, had been over-estimated. In this city
it was generally conceded that there were from
40,000 to 50,000 Chinese; and the majority in
the constitutional convention clearly acted on
the truth of that assumption when it voted to
exclude the Chinese from the apportionment for
representation. It now appears that the num-
ber of Chinese has been greatly exaggerated,
and that the percentage of Chinese to whites
is about 1 to 12. The proportion in several
other counties is much larger.

The news from many of the mining counties
of this State continues to be excellent. Re-
specting the Comstock mines, the latest advice
are encouraging, although the long-looked-for
developments have not yet been made. The
situation, however, is evidently improving.
According to the Gold Hill News the north end
is ripening for developments, while towards the
south the principal mines are progressing
towards a better condition.

The Condition of the Comstock.

The great Comstock appears to have lost its
prestige. Nearly every metropolitan journal
on the Atlantic side has indulged in vaticina-
tions as to the condition of the great lode, and
they see nothing but its inevitable collapse. They
have written Ichabod, and turned their faces in
other directions. Many of our own journals
have not done much better. They have as-
sumed, apparently, that the extraordinary diffi-
culties under which operations are carried on in
the principal mines of the Comstock have be-
come too great for the engineering skill and the
monetary strength of the coast, and that the
vast interest must succumb. Of course there
are many disagreeable truths in the record of
the Comstock mines. There is a long hiatus
since dividends were regularly declared and
paid. In many instances the management has
been reckless, to say the least. Assessments
have been levied and collected with a regularity
that is amazing, until the year's aggregate
presents a sum that is enormous. The reports
of the discovery of ore-bodies in any of the
mines upon which the hope or the faith of the
public was fixed, have been perfunctory and
altogether meager. And finally the great depth
of the leading mines; the extraordinary heat
arising from the high temperature of the water
and the imperfect ventilation of shafts and

But the situation of those mines is not, we
have reasons for believing, nearly so dismal as
has been generally represented. The great lode
has had its seasons of prosperity and adversity;
its times of depression and of reaction. People
will admit this, while they strenuously insist
that no cloud as dark as that which now lowers
upon it ever before so completely shut it out
from hope. This condition of mind results
surely from lapse of memory. Those people
forget the vicissitudes of fortune to which the
Comstock has been subjected. They seem not
to recollect the threatened collapse of 1865,
when the ore bodies began to show signs of ex-
haustion, and people left Virginia City by
hundreds. That memorable exodus partook of
the character of a stampede. Only one year
afterward important discoveries were made at
Gold Hill, and during several years thereafter
more than the old prosperity returned; mining
shares were active, and none doubted the Com-
stock. This good time lasted until about 1869,
when another period of depression set in, fol-
lowed by another flight of the doubters. Shortly
after this there came the splendid discovery of
ore in Crown Point and Belcher. The Com-
stock was voted immortal, and "high jinks"
was universal. Before the close of 1872 that
magnificent ore-body yielded to the drain of
dividends, and a sharp reaction followed those
bonanza days. This time the wolf had come.
When, lo! before the doubters had time to set-
tle down to enjoy the luxury of misery, Con.
Virginia produced such a boom as even the
Comstock had not known. The joy was as gen-
eral as it was sudden. Prosperity and happi-
ness walked hand in hand. Suddenly there

it, will yield nearly as large a profit as ore of
equal value found at 1,000 or 1,500 ft. The
extraordinary difficulties which are encountered,
such as extreme heat and vast volumes of
water, are met by unrivaled skill, energy and
means, and we do not doubt that they will be
overcome. Indeed, the temperature has al-
ready been reduced in the mines at the
north end, and will be generally mastered by
the perfect system of ventilation which is pro-
gressing. The heat has been the least difficulty
with which the engineers of the Comstock have
had to contend. How to check the inflow of
water, and how to lift it out, is the supreme
difficulty. We do not doubt that even that
problem will be successfully solved by the pa-
tience and skill of the experienced miners of
the Comstock.

Mineral King District, Tulare County.

[By J. W. A. WRIGHT.]

EDITORS PRESS:—A letter last summer gave
your readers some information about the ledges
and mines of the Mineral King district of
Tulare county. Its details were a record of
facts about a region of which little was then
known, and the facts were obtained from one of
its early pioneers. This sketch proposes to
give the results of some personal observations in
this remarkable and comparatively new mining
region of California, and is literally prepared on
the spot. The accurate map and an engraving
of one of its views which have been prepared to
accompany this account, will give your readers
a much more correct idea of numerous details
than any mere attempt at description could
possibly do.

For the better understanding of the engrav-
ing, the following explanation is necessary: 1
represents the upper tunnel of the Empire
mine, 3 is the Empire mill, 4 the town of Min-
eral King, 5 marks the smelting works of the
New England Co., where the former town site
of Beulah was located. You are looking east-
ward, the ravine in the middle is Monarch
canyon.

The map which Mr. P. Y. Baker (an experi-
enced and well-known surveyor of Tulare county)
has prepared covers about 20 square miles of
the principal part of the district, though its en-
tire extent, as first organized in September,
1873, is about 15 miles from east to west, by
the same distance north and south.

Though the "New England mining company"
did some work in this district by tunnel and
smelting works soon after its organization, all
their supplies were brought over the steepest
and most rugged of trails. Not till last year
was a road completed to this high region. By
the energy and perseverance of Thomas Fowler,
owner of the Empire mine, one of the most
promising claims upon its numerous ledges,
some 23 miles of road were completed during
five months of 1879, from April to August in-
clusive. Some of the greatest of natural obsta-
cles, and others, were overcome by this enter-
prise, at an actual outlay of not less than \$25,-
000 or \$30,000. Its completion has made easy
of access one of our highest and most precipitous
mountain regions, which undoubtedly abounds
in extensive ledges of various metals that must
eventually become valuable. More than this,
it has opened an almost *terra incognita* to the
tourist—whether pleasure seeker or student of
nature—which can be reached by comfortable
staging from Visalia in 14 hours, or by rail and
stage from San Francisco in less than 30 hours.

Location and Surroundings.

Being upon the very head waters of the east
fork of Kaweah river, among some of the high-
est mountains in California, the head waters of
Kern and King's rivers and the higher Sierras
around, Mt. Whitney can be more readily
reached by this route than by any other. A
trip with pack animals over safe trails, via
Farewell gap (see map), the little Kern,
the main Kern river and Whitney creek, makes the
top of Whitney itself easily accessible in a dis-
tance of about 60 miles from the town of Mineral
King. Of these advantages, future letters will
speak more fully.

As regards the exact location of the new
town of Mineral King, I am informed by Mr.
P. Y. Baker, who has run an important line
through the mountains, though no government
survey has yet sectioned the district, that it is
properly in Sec. 15, township 17 south, range
31 east. This makes its easting from Visalia
about 38 miles, its northing between 7 and 8
miles. Hence, in a direct line from Visalia,
it is about 39 miles, slightly north of east.

As regards the road, although its grade is
sometimes steep and its turns short, the road-
bed is as good and safe as in any of our mount-
ains. It has been put in thorough repair since
the serious injuries of last winter's storms.

Of the scenery presented at many points, we
can only ask space here to say it is extremely
grand and impressive, full of lofty, precipitous,
wild, deep, far-reaching views. Parts of it
vividly remind one of views along the Truckee,
the upper Sacramento, American river, Weber
canyon on the Overland route, and Alpine
scenery in Switzerland on the south side of Mt.
Gothard pass, where the great tunnel is being
made. But

The Subject of Absorbing Interest
Connected with Mineral King is its mines and
their successful development. Your readers
have already been informed that the ores of its

levels and drifts; the enormous and incen-
sant inflow of steaming water, the discharge of
which has severely taxed the most powerful
pumping machinery; all of these things have
combined to shake the confidence of even cool
and intelligent heads as to the practical question
of further successful mining on the Comstock.
These are some of the patent and disagreeable
truths which crop out of the last few years' his-
tory of the mines of the Comstock.

The very plans for the relief of the share-
holders of the mines, which have been suggested
at home as well as abroad, plainly indicate
either the loss of hope or the want of faith in
the revival of production on the Comstock.
Apart from the economy which would result
from co-operative working, the chief stress is
laid upon the utilization of the low-grade ores of
the mines. It has been proposed to extract
ores down to a specified depth at a rate of
wages to miners of about five-eighths of that paid
at present; and further, to devise a better
method than that now in vogue for their
cheaper and more thorough reduction. These
suggestions will beyond doubt be acted upon
some day. But before that time arrives, the
important question of the occurrence of bodies
of ore large enough and rich enough to pay the
enhanced cost of their exploration and extrac-
tion will have been practically and finally set-
tled. The bodies of low-grade ore which have
been passed over or cast aside in several of the
mines, be the aggregate amount great or little,
will yield few dividends to the holders of the
shares, and will induce fewer still to respond to
the call for assessments. That will practically
end large and productive mining on the Com-
stock.

came a tremendous blow from an unexpected
source, and brought gloom and foreboding. We
have no hesitation in saying that the disastrous
fire toward the close of 1875 was by all odds
the sharpest ordeal through which the fortunes
of the Comstock have yet passed. It was the
supreme shock to that great mining industry.
But it withstood even that. The unrivaled
ore-body in Con. Virginia and California con-
tinued to produce for some time, but exhaustion
waited upon the extraordinary output that was
necessary to pay that long series of splendid
dividends.

There have been no remarkable discoveries
since. But the history of the mines which we
have hastily sketched seems to us to warrant the
belief that valuable developments are likely to
occur any week. A cool head, familiar with
the history of the Comstock, will be slow to
believe that its glory has departed. Since the
discovery of the great lode there have been
half a dozen apparent collapses succeeded by as
many reactions or booms. It will hardly be
contended that the depth which has been
reached precludes the probability of further
discoveries of ore. No one doubts, we imagine,
that ore occurs at a great depth in Belcher, or
in one or two mines at the north end. Is it not
reasonable, and in strict accordance with the
history of all the large ore-bodies yet developed
on the Comstock, to believe that either of the
occurrences of ore specified may be the begin-
ning, the apex, of an ore-body in mass equal to
some of those found in the ground above? The
cost of working the mines at the increased
depth will be compensated in a large degree
by the improved machinery and the better
methods; so that ore found at 2,500 or 3,000

many ledges yield chiefly silver, lead, zinc, copper, antimony and gold, its mines being classed chiefly as silver mines. Many of its friends believe that its extensive veins are to become the future Comstocks and Virginias of this coast. Some miners contend that nothing but smelting will reduce these ores. This is no doubt true of the more "rebellious" forms which contain large percents of base metals. Others believe that there is much free milling ore here, of which that in the Empire mine is considered a fair type.

The New England smelting works, located in Harry's Bend, on the south side of the Kaweah, opposite the town of Mineral King, as shown on the map, are the only enterprise on a large scale for such reduction of these ores. For reasons not fully known, this costly experiment did not result satisfactorily, and these works have not been in operation for some time. Through Senator Fowler's exertions and influence,

A First-Class Silver Mill

Was erected so soon as the road was completed last fall. It was to work the Empire ore. The locations of this important mill and mine are shown on the map and engraving. The result of this experiment has been watched with much anxiety, as its success will largely develop the mining interests of Tulare county. Financial troubles intervened, and the heavy snows of last winter interfered. But it is cause for rejoicing among the friends of this valuable enterprise, that all these difficulties have now been removed, and mine and mill are again ready for active operations. The present Directors of this

Empire Gold and Silver Mining Co.

Are George W. Prescott, Walter N. Hawley, A. S. Halladie, Jacob S. Taher and Thomas

Harper considers this ore which comes from the greatest depth yet reached most similar to the Tuscarora and Northern Belle of Nevada, while the surface ore is more like the Comstock. As already mentioned in the Press, the average of nine assays made some 18 months since was \$121 silver and gold. Late assays, on which present opinions of the mine are based—opinions that have raised the value of its stock from nothing to \$20, give from \$20 to \$300 per ton silver and gold, of which the average amount in gold is \$4.

The Mill,

Which is now in first-class order, is in size and character like the Standard and Bulwer mills at Bodie, and the Mammoth mill. It has 15 stamps, 6 combination pans and 3 settlers, with 1 clean-up pan and settler. Its two engines consist of one 65-horse power for the pans and settlers, and one 35-horse power for the batteries. All this machinery is of the best quality, from Prescott, Scott & Co. The supply of wood and water for this mill and indeed through the whole district, is abundant. The total cost of the mill and all machinery to date is about \$200,000. There are so many objects of interest connected with this enterprise and its district, that further description of the mine, tramway, town of Mineral King, etc., must be reserved for a future letter, that your columns may not be overcrowded.

Various Assays and Work

Of some ledges named on the map are as follows: Black Wolf, \$52 silver, \$12 gold, 48% copper; Chihuahua, from \$100 to \$500 silver, \$12 gold; average amount of lead, 60%, though it sometimes amounts to 70%; White Chief, \$28 to \$300, tunnel in 195 ft.; Dolly Varden, \$112 silver, 38% lead, two shafts down, one 27 ft., the other 30; Mammoth, over \$300 silver, and

Letters from the Comstock.—No. 5.

EDITORS PRESS:—We may be right on the edge of the boom now—who knows? Stocks are being held up to a certain notch, and though the purchasers are few, the market is not allowed to go back. To an observing man there can be no doubt but that there is little more to be done at the north end in the shape of preparation. The "good ready" they have been getting on is nil fixed, and the time has about arrived for work. It is the general belief that Mackay has been mending his armor, riveting the seams and fixing the joints, so that he can sail into the fray with confidence.

On Saturday a crosscut was started in Sierra Nevada on the 2400 level, somewhere about 1,000 ft. north of the incline. It is running east, and will expose virgin ground; and it is thought that the 2500 level of Union Con. has drained the ground through which the crosscut will pass, so that there is but little danger of water. There will be no crosscutting on the 2500 level until the 2400 is reached. When Mackay was asked about the operations, he simply replied: "Tell the impatient fools we are going for the ore as soon as we can." Some people expect that the ore-body should be fully developed and ready to take out before any provision is made for the handling of water or ore. The work of sinking a shaft even makes some operators impatient. Inside of two weeks the crosscutting already begun at the north end and more about to begin, should strike something; something by the way which will send the stock down to \$2 or up to \$200. On this information people

GEN. GRANT AS A MINING PRESIDENT.—The country has been informed that Gen. Grant was lately elected President of the San Pedro and Canyon del Agua Mining Co. in New Mexico. This company is reported to own 40,000 acres of land in that Territory, and this immense tract is said to comprise mines of gold, silver and copper. It is alleged further that many Eastern capitalists are largely concerned in the gigantic enterprise. The character of the enterprise is thus set forth by the New York Tribune, the facts having been learned from Col. Grafton, of Washington. The San Pedro and Canyon del Agua Mining Co. is an incorporation organized under the laws of the State of Connecticut, with the following officers: President, George William Ballou; Vice-President, R. M. Pulsifer; Secretary and Treasurer, D. H. Darling; Superintendent, M. G. Gillette. It has capital of \$10,000,000, in 400,000 shares. Its property is situated about 36 miles southeast of Santa Fe, in New Mexico, and about 12 miles south of the Atchison and Topeka railway, which is now complete and in operation to and beyond that point. The company grants contain 42,000 acres of land. "This property," said Colonel Grafton, "was brought to my attention during the late war. In last October I learned it was in the market, and I secured an option of it. I sent an engineer to examine it and to report on it, and after receiving the reports I presented the matter to Mr. Ballou of Boston, who at once determined to organize a company for the purchase of the property, provided the reports made by my engineers were confirmed by him. We were fortunate in securing the services of Col. Gillette to examine the property, and after receiving his report we visited it, and the purchase by Mr. Ballou was

VIEW IN MINERAL KING MINING DISTRICT.

Fowler. The Supt. is R. B. Harper, well-known in the mining circles of California and Nevada. Mr. Harper has kindly given your correspondent every facility to learn for your columns the present condition of the company's valuable works. I have had the pleasure to accompany him through the mill and mine and to obtain all the details desired. First it should be known that the location of the mill is about 7,500 ft. above sea-level, while the upper tunnel of the mine from which the ore is taken is about 2,500 ft. higher, according to the best data that can be obtained, while surrounding ridges and peaks of the wildest and most craggy nature vary from 10,000 to over 13,000 ft. in altitude. Most of the slopes from these summits to the flat where the town and mill are located are at angles of 45°. These facts alone will give some conception of the natural difficulties that have been overcome. When work was suspended last December, Prescott, Scott & Co. recommended a

Careful Inspection of the Mine

By well-known mining men of San Francisco. Such examination was made in March and April by A. C. Lockhardt and R. B. Harper. Their report was favorable, and from it the present work has been done. This work embraces repairs of buildings and tramway, addition of hoisting works in the cave of the mine, and change in mode of working the mill. Everything is now unquestionably in first-class order for regular operations in mine and mill, and the latter began work Wednesday, the 28th, with 150 tons of excellent looking ore in the ore-house.

Character of the Ore.

Your correspondent has carefully examined this ore. It is entirely different from any ore previously worked from this mine, and is unlike any ore yet shown from the ledges of this district. It is in an extremely decomposed condition, showing considerable oxide of iron. It is full of black sulphurets of silver. No galena or "black jack" perceptible in it. Mr.

\$10 to \$35 gold; Lady Franklin, cap ore, \$20 to \$60, tunnel in about 40 ft., and ore from it assayed about \$82 silver. The Lady Emma ledge, in Monarch canyon, and not shown on map, assays from \$4.50 to \$150.

Beyond Farewell gap, near the head waters of the Little Kern river, are several promising ledges, not named on the map. These include the Occident, the Lakeside, Flagstaff, Bank Smasher, Lost Treasure, Bullion, and Broder and Bequette. On the latter claim a shaft is down 16 ft., and a tunnel on the Bullion is in 20 ft. The assays on some of these ledges are reputed to be fair, though their exact figures cannot be obtained.

In All Over 200 Claims

Have already been located and recorded in this district, as I am informed by Mr. George Carrington, Recorder of the district.

The sharp, saw-tooth peak, seen in the distance through the canyon, is Miner's Peak.

The highest near here, and perhaps over 13,000 ft. high. The engraving is prepared from two photographs, and on such it is difficult to represent perspective correctly. Hence, Miner's Peak looks lower than adjoining ridges to right and left. In reality it towers far above them, and only looks lower because it is more distant. It is one of the highest peaks of the Sierras and is a noted landmark, as seen from the greater part of the plains in Tulare and Fresno counties. Your readers will learn more about this grand peak and its surroundings in future letters.

Mineral King, July 26th.

ADMIRAL AMMEN has addressed a letter to the President of the American Geographical Society, in which he says that the Nicaragua canal will follow the Lagos route, and only cost \$45,000,000.

NEW ZEALAND has now over 1,100 miles of railway, all built within about 12 years, and all narrow-gauge or three feet six inches.

can "short" or "long" as may best suit them. The man who has a choice is entitled to put up his money on it.

The talk about working low-grade ores seems about to be settled. Private individuals who are out of work simply go to the waste dumps, cart away the rock, and do the best they can with it after the fashion of primitive times. In many of the dumps they are liable to strike \$30 rock, which won't need much blasting either.

The Quinn mine continues to attract attention in a style that is making the insiders madder and madder every day. About a year ago a few men who held the stock considered they had indications which, if properly manipulated, would result in a little deal. They proposed to put it up not over \$3, which was then considered pretty good for Quinn. They made little progress, however, and, believing it would never do to put the stock up unless there was some merit, they let it go for anything. After that they struck it, and then attempted to get the stock in, and some partially succeeded, but hardly as well as they wished. Some insider is supposed to have "blabbed," and now they stand a chance of seeing the stock reach \$10, with "dead loads" of it held by outsiders, who are about as well posted as anybody on its value.

HAND DRILL.

THE MYSTERY EXPLAINED.—A patron of the Oakland water company, who has a fine residence in that city, informs us that he has entire faith that the noted Dr. Tanner will succeed in fasting 40 days and 40 nights without the least danger of dying for the want of nourishment if supplied with the very strong water furnished our neighboring city. If any person doubts our friend, a smell of the reservoir, or even the water from them, will be convincing. It is proper to add that the company's water also smells very bad of extortionate prices, seriously detrimental to the welfare and future growth of Oakland.

consummated, and a company organized. Copper, silver and gold were found upon it, and the mines were worked extensively in 1839 and 1842 by Mexicans, who carried their water for washing the gravel on the backs of donkeys. Hydraulic engineers have been employed by the company to bring water from the Sandia mountains to the placer mines. The work will be commenced about the 1st of October. A large smelting establishment for the reduction of the silver, will be erected and in operation by that time."

UNION CONSOLIDATED YIELD.—The north end of the Comstock is not yet absolutely barren. The annual statement of the Union Con., which was lately published, shows that during the past year, and up to June 30, 1880, the mine has produced 30,019 tons of ore, all of which has been milled, and has yielded the sum of \$1,174,803.45, or \$39.13 per ton, that being 81% of the assay value, no allowance being made for moisture. The value of the gold in the hullion was \$566,465.59, and of silver, \$608,337.86. This ore was all taken from the ore body lying on the northern boundary, which was first discovered in the Sierra Nevada incline, 19,781 tons being extracted from the 2300 level and 10,238 tons from the 2400 level.

HOPE FOR THE CASTAWAYS.—The lively interest felt in this city for the safety of the crew of the foundered ship *Mathilde*, who are supposed to be on the island of Socorro, lying off the Mexican coast, was intensified by the graceful act of an English gentleman. As soon as he learned of the probable fate of the castaways, Sir Thomas Hasketh dispatched his steam yacht, *Lancashire Witch*, to their rescue. The yacht sailed on Wednesday. At the same time the government sailing yacht *Freda*, was dispatched by special order of the Secretary of the Navy, on the same errand of mercy.

Entry of Public Lands.

Commissioner Williamson, of the General Land Office, has issued the following letter of explanation and construction of the scope and force of the act of Congress relating to the public lands of the United States:

To Registers and Receivers of the United States District Land Office:—I have to direct your attention to the provisions of an act of Congress, approved June 15, 1880, entitled "An act relating to public lands of the United States," of which a copy is appended. Section 1 provides that when any lands of the United States shall have been entered, and the Government price paid therefor, no action shall be had or further maintained for or on account of certain trespasses therein specified. The first proviso to this section restricts its application to trespasses of a date prior to March 1, 1879. This section extends to such trespassers the privilege of paying for lands upon which the specified offenses were so committed, at the price per acre for which, under the law in force at the date of payment, the lands could be sold.

This privilege of purchase is not confined to the lands subject to private entry, but extends to any lands, not mineral and subject to disposition, under the general existing laws. This section cannot be construed to permit a party who falls within the class of offenders named to enter land if the valid claim of another person shall have attached prior to his application to purchase and is still subsiding. Whenever an application shall be made to purchase under this section, you will require the same to be presented under the oath of the applicant, giving a full and detailed statement of all the facts upon which he bases his claim to purchase. Such sworn statement should be corroborated by the affidavits of credible witnesses, and you will thereupon forward the papers in a special letter to this office, allowing no entry until so directed by me. Under Sec. 2, duly qualified persons who, prior to June 15, 1880, entered, under any of the homestead laws, lands properly subject to such entry, are permitted to obtain title by paying the Government price, less the fee and commissions paid at the date of original entry. When homestead entries made prior to June 15, 1880, have been attempted to be transferred by a bona fide instrument in writing, persons to whom such transfers were made are likewise authorized to obtain title by like payments, and with like deductions of fees and commissions.

In allowing entries of the first-named class you will require proof that the party was 20 years of age, had declared his intention to become a citizen of the United States, and was in other respects entitled to make the entry. In permitting entries by transferees you will require the instrument in writing, by which it was sought to transfer such homestead right, to be filed together with the best evidence attainable of the bona fide character of the transfer, including the affidavit of the party who seeks to purchase. You will exercise all possible care in this matter, as it is not improbable that the proper execution of the law will largely depend upon your vigilance and discretion. In cases wherein you entertain a doubt of the propriety of allowing the application to purchase, you should refer all papers to this office with a full statement of facts and your opinion. Under the proviso for this section you are specially instructed to allow no entry which interferes with any entry of land under the homestead laws made subsequent to the original entry, on which the application is made to enter under Sec. 2, and if the land was embraced in the prior entry at the date of such homestead, the section is in operation, inasmuch as in that case the land was not properly subject to entry.

The application to purchase must likewise be rejected if, at the date of the original homestead entry, a prior claim, which has not been abandoned or forfeited, existed. Under any law, I do not construe this section as intended to permit the parties named as conditional purchasers to make an entry of tracts to which adverse legal rights have attached prior to the date of the act. The third section reduces to \$1.25 per acre the price of any lands, which were subject to ordinary private entry, at \$2.50 per acre at the date of approval of the act, having been doubled in price by reason of the grant of alternate sections for railroad purposes, and which were put in market at that price prior to January 1, 1881. Lands which have not been put in market for sale at ordinary private entry at \$2.50 per acre, or which were so put in the market subsequent to the 1st of January, 1881, are not changed in price by this section. You will carefully observe the rule as to price thus introduced. By reference to your official records it will be in your power to ascertain the facts with regard to any lands from which to decide as to its applicability to them. In case of doubt you may correct your records to exhibit the facts by correspondence with this office. You will further observe that under section 4 none of the provisions of this act apply to mineral lands, and that no person is entitled to the benefit of any provisions of the act who falls within the inhibition named in this section.

COMPRESSED AIR LOCOMOTIVE.—Lately a number of persons assembled at Woolwich Arsenal, England, for the purpose of witnessing tests of a compressed air engine invented and patented by Col. Beaumont, R. E. The engine

is merely an experimental one, though others of a better shape have already been made. The motive principle is compressed air, the difficulties in the application of which Col. Beaumont has, after some years of experiment, succeeded in overcoming, and has at last constructed an engine in which the entire power stored up in compressed air can be utilized, no matter how high the pressure may be. The engine is designed for use upon tramways, underground railways, or any line of rails on which smoke, steam and noise are objectionable. The air having first been compressed by a stationary engine, is stored in the reservoir under a pressure of 1,000 lbs. per square inch, whence it passes through three cylinders, and is finally noiselessly ejected into the atmosphere. After a brief explanation by Col. Beaumont, a carriage was attached to the engine, on which the company took seats, and several runs were made along the metals in the arsenal for a distance of about one-third of a mile. The result was that the mile was accomplished in something under five minutes, making allowances for frequent stoppages, owing to the rails being in use and the general roughness of the arrangements. This was done at a loss of only 200 lbs., the gauge showing 1,000 at starting and 800 after a run of four miles. But this is by no means a test of the capabilities of the engine, which has been so constructed as to attain a speed of 25 miles an hour, and to run for 22 miles with one charge of compressed air. This engine is perfectly noiseless, completely under control, and seems destined to very considerably modify, if not to supersede, some of the modes of traction now in general use.—*Colliery Guardian*.

SCIENTIFIC LUMBERING.—The rapid disappearance of our forests renders every effort at economizing in the production of lumber a matter of very considerable general interest. The progress made in this direction has been summed up by an Eastern contemporary as follows: Where 20, or even 10, years ago, half an inch of timber was turned into sawdust for each board cut from a log, the best modern practice gets along with a waste in this way of only one-quarter, and in many cases, with one-eighth of an inch. The mills that are not supplied with lath machinery, splatters, wood saws, etc., for the purpose of working up all this refuse and giving it a market value, are considered to be but meagerly equipped; and unless they have some special advantage in the way of cheap timber or cheap transportation, are soon distanced in the race by their less wasteful competitors. The economy of lumber production, however, does not all lie in securing the greatest amount of marketable stuff from the least timber. Logs are hurried along from the water to the pile of finished lumber, with a rapidity that the pioneer lumberman of the northwest would have thought impossible when they first planted a sawmill alongside of western waters. The progress made even in the past 10 years is something remarkable. It was a comparatively rare thing in 1870 to find a mill man who brought logs into the mill, sawed them up with circular and gang, edged and trimmed the lumber, and carried outside the mill almost entirely without the aid of human brawn.

INDEPENDENCE LAKE.—This delightful sheet of water, on the eastern slope of the Sierras, is unexcelled either in beauty or attraction, says the *Truckee Republican*. The lake is surrounded by high mountain peaks, some of them still covered by heavy bodies of snow. The inlets to the lake are now filled with little torrents of water just off the snow. We cannot conceive of a locality possessing more delightful views than are presented at Independence. But the chief attraction there is the fishing facilities. Elegant boats and fishing tackle free, and the lake is conceded to be the best fishing ground in the State. The forests surrounding are also said to be well supplied with game. Deer are just making their appearance, and are said to be quite plentiful.

A NEW PHASE OF DECORATIVE ART.—Some of the semi-scientific idlers at Nahant, says the *Springfield Republican*, have taken to cherishing families of decorated crabs. The plan is to treat the newly captured crab to a hard scouring with a nail brush until his shell is perfectly clean; when he is placed in a jar with a quantity of sea-weed. As soon the bewildered crab recovers his senses, he seizes a bit of weed, bites it off, covers it with some sticky substance from his mouth, and presses the end upon the shell on his back; and there it sticks and grows. The idea of the poor crustacea is to hide himself from the sharks and rays that like to make a dinner off of him, and he keeps up the process until he looks like a moss-covered rock.

VALENTINE LAND SCRIP.—Secretary Schurz has rendered an important decision respecting this notorious land scrip. A dispatch from Washington of the 19th inst. says that the Secretary has just sent in his decision confirming that of the Commissioner of the General Land Office, which denied the application of certain parties to locate Valentine scrip on land in San Francisco. In his decision Secretary Schurz holds that the questions proposed were settled adversely to the claimants in precisely similar cases in Chicago, and there is no ground for going over it again, inasmuch as neither the city of San Francisco, the State of California nor the United States demand a reconsideration of it.

THE SADDLE AGAINST THE BUGGY.—The memory of man extendeth to the day when the boys on the farm were proud to ride a fine young horse to church or to see the girls. His took pride in the colts and taught them to move freely under the saddle, and above all, when the colt was broken he was taught to walk. Now, the boys must have a fine buggy and harness, and the colt must show his style and speed all this time. The boy is in too great a hurry to allow the colt to walk. The colt, buggy and boy are soon a used-up set by fast driving. The whole business of buggy riding by farmers' boys is expensive, extravagant and demoralizing. Not one farmer in ten can afford such a turnout for the lad. Many of them buy a buggy and let it stand in the sun and storm. They are too poor to have a house for vehicles. Some men cannot afford the luxury of a buggy. If we could return to the fashion of riding on horseback we would save millions to the farmers, and the boys and girls would develop better forms and have better health. Any lazy lout can ride in a buggy, but to be a graceful rider on horseback one must have some energy and get up in his nature. There is life and health in riding on horseback. The whole system feels the invigorating effect of it. The rider and the horse catch the fire of sympathy and excitement in the run or fast paces, and every nerve and muscle of the body is brought into healthful invigorating play. This mania for trotting horses has been felt on every farm in the land. The country is full of road horses that some man or boy loves to pull the string on. They are usually poor saddlers, slow walkers, and rough. We need a reform. The place to begin is in breeding a class of horses of good size, style and action, that can move freely in more than one gait. The English market is open for such horses. The well-knit horse of good style and action, suitable for a hunter or a carriage, will bring better prices than our average horse. The farmer will find it to his interest to raise a class of colts that the boys will like to ride. He can raise three or four fine saddle-colts for what one buggy and harness will cost, and a fair saddle-horse will bring more than the average roadster.—*Nashville American*.

SANITARY INSPECTION IN PARIS.—The statement recently made by Edward Griffiths, C. E., says the *London Telegraph*, upon the frightfully insanitary state of many new and handsome London houses, may well alarm the public. A cheap and easy method of obtaining a report on the pipes and drains of the house, and of rectifying them if defective, should be within the reach of every proposing tenant. The plan pursued in Paris, which secures impartiality in the inspectors, and which was noticed by one of the speakers at the recent conference, might, with advantage, be transferred to London. The inspector is taken from a different part of the city to that where he is to make a report. He is sent to a house and told to examine its sanitary condition, without any information being supplied to him as to who is setting him in motion, whether the landlord, the tenant or his official superior, and he knows not whether he may not be sent to test his own efficiency or to confirm a previous report by some colleague. By these means collusion between inspector and builder, or inspector and landlord, is at all events rendered improbable.

OXYGEN.

What is it? Everybody knows it is as essential to life as food itself. Yet when people are ill for the very want of revitalization through respiration, they dose themselves with drugs and bitters to the effect of demoralization! All Invalids should read Dr. STARKEY & PALEN'S (Phila.) *Treatise on Oxygen*, which is sent free to all who may ask for it. The subject is worthy of investigation. References to physicians in San Francisco, who use and prescribe Compound Oxygen in practice. As prepared for home use (conveniently sent to any address) it may be obtained of H. E. MATHEWS, 606 Montgomery street, S. F., upon the same terms as furnished by Drs. Starkey & Palen, Philadelphia, Penn. Complete instructions with each package.

Sanderson Bros. & Co.'s**BEST REFINED CAST-STEEL,**

WARRANTED MOST SUPERIOR FOR DRILLS, HAMMERS, ETC.

A full and complete stock of this reliable and well-known brand of Steel, for mining and
other uses, now in stock, and for sale at

21 and 23 Fremont Street, S. F., - H. D. Morris, Agent.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and
of the best material. All sizes kept constantly on hand.**SHEET IRON PIPE.**Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe.
Also, Galvanized Iron Bollers, from 25 to 100 Gallons.Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools
supplied for making Pipes. Estimates given when required. Are prepared for coating all size of
Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

SHEET IRON PIPE.

**STEEL
CASTINGS**

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and
durability.
An invaluable substitute for forgings or cast-iron requiring three-fold
strength.
Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Loco-
motives, etc.
15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running
prove its superiority over all other Steel Castings.
CRANK SHAFTS, CROSSHEADS and GEARING, specialties.
Circulars and Price Lists free. Address**CHESTER STEEL CASTINGS CO.**

Copp's Hand-Book of Mining Laws.Henry N. Copp's hand-book of mining laws, just issued,
contains the United States mining laws and instructions
thereunder, a digest of decisions, forms, list of mining
patents issued, etc. The digest of decisions alone is a
very valuable thing, giving, as it does, in brief form, all
the decisions of the Secretary of the Interior and Com-
missioner of the General Land Office in relation to mining
matters. These are all under proper headings for easy
reference. Forms are given for notice of location, proof
of labor, notice of forfeiture, miners' lien, application for
survey, patent, etc., affidavit of improvements, etc.
There is also a list of patents issued for mining claims
from July 26th, 1866, to August 1st, 1877. The book is
of pocket size and very convenient for all who are inter-
ested in mines. It will be sent post-paid for \$1, on ap-
plication to Dewey & Co., 202 Sansome street, San Francisco**A Card from Architects.****The California Architect and
Building Review.**

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from
prominent Architects in this city.Believing that a journal of this kind is a necessity on this
coast, and judging from what has appeared in the "Quarterly
Architectural Review," we are led to believe that the
CALIFORNIA ARCHITECT AND BUILDING REVIEW
will be worthy of generous support and encouragement. We
therefore pledge our cordial sympathies, personally, and hope
that the enterprise will receive kindly recognition and liberal
support from all Architects and Builders and the public gen-
erally. (Signed) David Farquharson, Wright & Sanders, S.

230,167.—PROPELLING SHIPS.—F. Von Leicht, S. F.
2,312.—LABEL.—A. W. Stone, San Quentin, Cal.

List of Canadian Patents issued to Pacific Coast Inventors:

- 11,193.—BLASTING POWDER.—J. Pattison, Nevada, Cal., April 24, 1880.
11,274.—PILLOW SHAM FRAME.—J. B. Adams, Oakland, Cal., May 26, 1880.
11,319.—HARROW.—N. Valley, Jr., S. F., June 5, 1880.
11,331.—AXLE.—E. A. Wible, Folsom, Cal., June 5, 1880.
11,374.—NEWSPAPER HOLDERS.—W. C. Fitch and C. Day, Sacramento, Cal., June 14, 1880.
11,404.—ART ALBUM.—E. S. Glover, Portland, Ogn., June 19, 1880.
11,409.—Piston Packing.—Oso. C. Phillips, Silver City, Nev., June 19, 1880.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

BERRY BASKET.—Roswell E. Morey, S. F. Patented July 13, 1880. No. 229,904. This invention relates to that class of berry baskets made of bent veneers, and provided with a sheet-metal rim crimped over the edge. Heretofore the sheet-metal rims have simply been bent at the corners, and experience shows that when the baskets are of the larger sizes need the bends at the corners of the sheet-metal strip are too weak to retain the basket in its proper form, and in handling it changes form. The object of this invention is to overcome this difficulty, and it consists in casing within the sheet-metal rim, at its corners, a brace or strengthening plug of solder, or other metal or alloy, which makes the corners solid, and greatly strengthens the strip and enhances its capacity for preventing the top or rim of the basket or box from changing form.

WINDMILL.—Joseph H. Therian, of Orland, Colusa county, Cal. Patented July 20, 1880. No. 230,209. This device consists of a novel exterior rim for the wheel to which the vanes are hinged, this rim being made in zigzag sections, and having the arms or spokes of the wheel extending from the hub to the angles of these sections, so that they stand alternately forward and backward from a plane, and thus brace the rim. It also consists in a novel formation of the vanes, which are curved similar to a plowshare, and are hinged to this angular rim, so as to stand diagonally with the plane of the wheel, and they may be adjusted to the strength of the wind by means of arms connected with a ring or sleeve sliding upon the shaft. It further consists of a peculiar socket by which the mill may be mounted upon a single post, this socket having a vertical spindle upon which the wheel, axle and upper part of the mill may be mounted to swivel about as the wind may make it necessary.

GANG-PLOW.—Henry A. Olmster, Oakland, Cal. Patented July 20, 1880. No. 230,192. This invention consists in a means of adjusting the cut of the plows and holding them down. Ordinarily, in gang-plows with rigid beams, when they are lifted out of the ground the heels of the plows are apt to drag on the ground. This cannot occur in the present device, since the raising of the loose plow-beams elevates the points of the plows, and the elevation of guides lifts the rear ends. Each of the plows hangs loose and independent, and while they are lifted together, held down together, and have their depth of cut simultaneously regulated, each has an independent motion as well, so that one can go over a mound or ridge and not affect the other. The adjustment of the plows is all regulated from the driver's seat.

SHEEP-SHEARS.—John G. Corey, Santa Paula, Ventura Co., Cal. Patented July 13, 1880. No. 229,872. This device consists in a novel means for adjusting the tension of the spring, so that any pair of shears may be adjusted from the lightest to the heaviest tension, to suit the hand of the operator, and to regulate them so as to be used in light, heavy, or dirty wool.

THE MECHANICS' FAIR.

New and Interesting Features.—Prospects of Unusual Success.

OPENS AUGUST 10th, 1880.

The Fifteenth Industrial Exhibition of the Mechanics' Institute of San Francisco will open with all the usual formalities, on Tuesday, August 10, 1880. The Managers of the Institute have put forth extra exertions to make this year's exhibition of superior usefulness and interest—and a fitting exponent of the character of our fields, our workshops and of our social and æsthetic life. Circulars have been issued clearly and fully announcing the purposes and expectations of the management, and calling upon all the varied industrial interests of the State, and of the entire Pacific coast, to come forward and make the exhibition of this year one which shall excel all that have preceded it.

It is confidently expected that the liberal offer of premiums of gold, silver and bronze, and diplomas, and cash will present an additional inducement for exhibitors to come forward and put forth their best efforts to secure such a combination of attractions as cannot fail to call out an unusually large number of visitors from both city and country.

One of the leading features of the fair will be

The Horticultural Display.

To effect this, an arrangement has been made with the California State Horticultural Society, to take special charge of this interesting department and make it an exhibition which shall be worthy of our State, and a proper representative of its grand horticultural interests. This portion of the exhibit will be wholly under the charge of the Horticultural Society, and the appointment of Judges will be made with reference to their special fitness for the examination of the exhibits entrusted to them. The premiums will be awarded by the Institute solely upon the recommendation of such committees as the society shall appoint. All persons engaged in horticulture, whether as professional or amateur, are invited to do what they can towards making the exhibit comprehensive and representative.

Horticultural Premium List.

PLANTS, TREES AND FLOWERS.

- To the exhibitor making the best and most attractive continuous display of plants and flowers during the exhibition..... Silver medal and \$75
Second do..... Bronze medal and 50
To the exhibitor making the best display of foliage, plants and ferns..... Silver medal and 50
Second do..... Bronze medal and 25
Best group of hardy palms and araucarias..... Bronze medal and 25
Best group of orange or lemon trees, rarely, bright and growth considered (not less than 10 specimens)..... Silver medal and 25
Best display of tuberoses in bloom in pots (not less than 25 plants)..... Bronze medal and 15
Best continuous display of cut flowers during the exhibition..... Silver medal and 35
Second do..... Bronze medal and 20
Best continuous display of gladioli (not less than 40 glasses)..... Bronze medal and 25
Second do..... Diploma and 10
Best display and variety of dahlias..... Bronze medal and 25
Second do..... Diploma and 10
Best display of ornamental grasses..... Bronze medal and 15
Best display of rustic work and filling..... Silver medal and 30
Best single specimen of rustic work and filling..... Diploma and 10

OPEN TO AMATEURS ONLY.

Best 12 house plants, \$10; Best display of cut roses, \$10; Best specimen of climber on globe or trellis, \$5; Best collection cut flowers, \$10; Best carnations, \$5; Best 12 variegated-leaf geraniums, \$10.

FRUIT—OPEN TO GROWERS ONLY.

N. B.—No premium will be awarded unless the fruit is properly named.

Best collection apples, \$20; Best 12 varieties apples, \$10; Best collection pears, \$20; Best 12 varieties pears, \$10; Best collection peaches, \$20; Best 6 varieties peaches, \$10; Best 6 varieties canning peaches, \$10; Best collection plums, \$10; Second do, \$5; Best collection prunes, \$10; Best collection nectarines, \$5; Best collection quinces, \$5; Best collection figs, \$10; Best collection oranges, \$15; Best collection lemons, \$10; Best collection limes, \$5; Best display of grapes, \$25; Best collection table grapes, \$15; Best 6 varieties table grapes, \$10; Best collection wine grapes, \$20; Best 6 varieties wine grapes, \$10; Best collection raisin grapes, \$15; Best collection seedless raisin grapes, \$15; Best display Japan persimmons, \$10; Best display pomegranates, \$5; Best display blackberries, \$5; Best display raspberries, \$5; Best display strawberries, \$5.

DRIED FRUIT.

Apricots, best 10 lbs, \$5; Apples, best 10 lbs, \$5; Prunes, best 10 lbs, \$5; Peaches, best 10 lbs, \$5; Plums, best 10 lbs, \$5.

\$5; Pears, best 10 lbs, \$5; Figs, best 10 lbs, \$5; Raisins, Cal., best box of 20 lbs. or more, \$25; Seedless raisins, Cal., best box of 20 lbs. or more, \$15.

NUTS—CALIFORNIA GROWN.

Almonds, best 10 lbs, \$5; Walnuts, best 10 lbs, \$5; Chestnuts, best 10 lbs, \$5.

The officers of the California State Horticultural Society are as follows: Board of Directors—E. W. Hilgard (President), W. B. West, J. Strentzel, John Rock, C. H. Shinn, E. J. Wickson (Secretary).

All intending exhibitors are requested to announce at once what exhibits they expect to make, to the Secretary, E. J. Wickson, 414 Clay street, San Francisco.

The State Viticultural Society.

Established by the last Legislature, is also to have a special department to itself, immediately adjoining the horticultural exhibit. The rules governing this exhibit are to be left to the exhibitors themselves. There will also be a trial-room set apart and furnished, where, on special days, the wines exhibited may be tried by experts. A complete and comprehensive report will be made of each exhibit, and printed in full in the regular proceedings of the Institute. This, alone, will more than pay the exhibitor for all his trouble. It is to be hoped that all producers of the expressed products of the vineyards of California will take pride in sending the best they have, that a large and fine display may be made. Especially is this desirable at the present time, in view of the large number of European and Eastern visitors who expect to examine our products. The officers and members of this Board are as follows:

Arpad Haraszty (President); Charles A. Watmors (Vice-President); Chas. Krug (Treasurer); J. DeBarth Shorb, Isaac DeTurk, R. B. Blowers, Geo. West, Stockton, L. J. Rose, G. G. Blanchard. Dr. John I. Bleasdale, Secretary.

Manufactures and Inventions.

In addition to the productions of the soil and vineyard, there will be a grand gathering of the results of the manufacturing skill of our artisans. Inventors will also be there with their novelties in every line of mechanism. It is most certain that the

Display of Mining Machinery

Will be the most complete and extensive which has been seen in this city for the last 10 years—the whole presenting a complete embodiment of the brain work and inventive and mechanical skill of the Pacific coast. The officers and managers of the exhibition are: P. B. Cornwall, President; A. W. Starbird, Vice-President; J. A. Bauer, Treasurer; J. H. Culver, Secretary, and J. H. Gilman, Superintendent. The Board of Managers is composed of the following gentlemen: A. L. Fish, C. Waterhouse, James Drury, Nathaniel Hunter, F. A. Frank, David Kerr, Samuel Dinmore, J. R. Wilcox, Geo. H. Hopps, Edwin Fretwell and George Spaulding.

The pavilion will be brilliantly lighted with electricity and gas, forming a lively magnificent scene in the evening.

Applications for Space

Should be made at once to J. H. Culver, Sec'y, 27 Post street, San Francisco. The pavilion is now open for the reception of goods. The exhibition opens August 10th and all articles for competition must be in place not later than Friday, August 13th. Space allotted and not occupied by August 7th may be given to others. No charge to exhibitors for space, steam or water.

Goods for exhibition should be addressed, Mechanics' Fair, San Francisco.

Exhibitors should take great care to have their goods properly in place in the Pavilion at an early day. No articles will be received for competition later than August 13th.

Rates of Admission.

Double Season Tickets.....\$5.00
Single Season Tickets.....3.00
Children's Season Tickets.....1.50
Apprentice's Season Tickets.....1.50
Single Admission, Adults......50
Single Admission, Children......25

Award of Medals.

In addition to 62 cash premiums, varying in amounts from \$5 to \$75, the Institute offers 40 gold medals, 313 silver medals, 215 bronze medals and 92 diplomas. The full premium list will be given next week; or it may be had at any time on application to J. H. Culver, Sec'y, 27 Post street.

IMPORTANT TO VISITORS.

To visitors this exhibition will offer a combination of attractions, such as has never before been presented to the public of California, and far more than sufficient to repay them for their outlay. This display of the natural productions alone of this coast will be more in value to them than the cost of a season ticket. The Pavilion, during this exhibition, will not only be pleasing to the eyes and a pleasant place of resort and social reunion, but it may also be made a most important educational medium, and such a one as no one who desires to store his mind with useful information can afford to neglect.

GOLD MINING IN ILLINOIS.—Again the report comes from Chicago that placer gold mines have been discovered and are profitably worked in Logan Co., Illinois. The *Journal* says there seems to be no doubt of the fact that particles of gold—veritable, genuine gold—have for some years been picked up from the bed of a stream which runs through a series of broken and barren hills in that locality; but it is still a question whether the find is of sufficient importance to justify great expectations.

THE CLAYTON AIR COMPRESSOR.—We notice that the Hudson River Tunnel Co. have made a contract with Mr. Clayton, of Brooklyn, N. Y., for furnishing whatever additional air compressors may be needed in the future prosecution of important work. By a circular before us from the Chief Engineer of the Tunnel Co., we learn that the Clayton compressor is doing its work admirably well.

PITTSBURG contains 40% of the entire glass industry of the country.

News in Brief.

THE Chinese have named their war vessels after the letters of the Greek alphabet.

A good many Scotch and English, with money enough, are settling in Manitoba.

NEARLY all the tramps have disappeared from along the line of the overland railroad.

MEISSONIER declined the proposition made him to paint panoramas for an American showman.

At the Swiss Universities this year the female students have carried off most of the prizes.

GREECE has a little navy, comprising two iron-clads, manned by 384 sailors and commanded by 269 officers.

A HARTFORD man, while talking through a telephone during a thunder-shower, was knocked down by electricity.

A FIRE broke out at 12 o'clock, July 23d, which destroyed the entire business portion of Gibsonsville, Sierra county.

A CONTEMPORARY estimates the number of persons who are said to have lived for 40 days and 40 nights without food at 10,000.

THE Yellowstone *Journal*, Montana, says a St. Paul trader has brought there this season 2½ tons of beaver skins and other pelts in proportion.

THE Navy Department received dispatches from Admiral Wyman, which exonerates the Spanish steamer *Canto* for firing upon American vessels.

SINCE the water has receded in the Yuba river opposite Marysville, immense sand bars afford an indication of the debris deposited the past season.

A CENSUS enumerator says that this averages Plymouth county, Mass., farm, worked by a man and family, will not produce more than \$300 a year.

Two oil wells are being bored at Santa Cruz, and six more are being got ready for drill. The cost of boring, etc., for each well is from \$3,000 to \$4,000.

THE Supervisors of Yolo county have appointed a veterinary surgeon to examine the horses in this county and report all cases of glanders found.

A BUCK was recently shot some 10 miles from Red Bluff, on whose head are three antlers, having a number of prongs, making a perfect network of horns.

THE Philadelphia school of design for women has purchased the Forrest mansion, and this is said to supply the trustees of the Forrest home with needed funds.

THE trade between England and Greece consists of exchanging cotton goods for dried currants. The sum of these exports has scarcely changed in 10 years.

COLONEL VALLE of the Mexican army has taken the field against Victorio. He has permission from Washington to cross the Rio Grande if necessary.

AN Indians farmer says that labor has not been so scarce and high-priced in 65 years, and instances the employment of two women in his harvest fields at \$2 a day as proof.

A MANUFACTURER of Scotch caps and felt hats in Scotland has bought a factory in Vineland, N. J., to which he will remove all his machinery and hands this fall, bag and baggage.

THE steamer *Mamie*, having on board a party of excursionists, mostly altar boys at Trinity church, Detroit, was run down by the steamer *Garland* on the Detroit river, July 22d.

A M. NORCROSS, of Norwich, has set two hens, each with 12 eggs, dedicated one to Hancock and one to Garfield, and the most successful hen will determine how he will vote.

A NEBRASKA Sunday-school boy, on a picnic, leaned out of a car window and fired off a revolver. The ball killed a little girl who had just put her head out of another window.

So great was the vulgar curiosity to see the negro murderer Price hanged in Cincinnati, that white women, in order to gain admission, declared themselves negroes, and related to the criminal.

A KANSAS paper tells of a wild woman living along the Moccasin river. Her tracks have been found in the sand along the shore. Sometimes she wears shoes, and other times she goes in her bare feet.

IN the English fashion papers all the women depicted look cross and sour, while in our papers all the ladies are too lovely for anything, and look as though butter would not melt in their mouths.

PAINTING on kid is a favorite pastime with Parisian ladies, and bracelets, chatelains bags and belts of silk and white kid, painted with flowers and classic heads and mounted with gold and silver, are very popular.

A RECORD OF SCIENTIFIC PROGRESS.—We have received from the publisher the first number of *Science*, a weekly record of scientific progress. It is a well-printed quarto of 12 pages, enclosed in a cover. The editor is Mr. John Michels, and it is published at 229 Broadway, N. Y. *Science* counts among its list of expected contributors some of our most distinguished scientific writers and experts. The opening number contains several valuable papers, among the list being a brief monograph on the United States Naval Observatory, by Prof. Holden; "Electricity as Power," by Francis P. Upton; and "Errors of Refraction in the Eyes of Microscopists," by Dr. J. C. Morgan. There is besides a number of instructive paragraphs of scientific miscellany. It promises to be an attractive record.

The Mechanics' Fair Daily.

FAIR OPENS AUGUST 10, 1880.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the ELEVENTH VOLUME of the MECHANICS' FAIR DAILY during the FIFTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Tuesday, August 10th, 1880.

It will be of good size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resources and rapid progress of our great Western Community.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its column command when brought into the shop and family circle by those who receive it freely at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive advertising and printing privileges, and will receive no advertising in the official catalogue and reports.

Our ten previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a mere broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our coast.

PERFECT METALLURGICAL WORKS.—There can be no doubt that the metallurgical works of San Francisco are absolutely perfect, both in their apparatus and the theoretical and practical skill of their managers. There are several snob establishments in the city, but as an example we will take the star works of Kustel & Riotte. It is simply perfect in equipment, and unrivalled in its large and skillful treatment of every variety of ore. There are rock-breaker, stamp mill, muffle, smelting, cupelling and roasting furnaces, amalgamating and grinding pans and barrels, and means for chlorination and lixiviation, and every approved process for treating gold and silver ores. There is a complete analytical laboratory, and a series of perfectly adjusted scales. And all these tools and means are in the hands of men who are both scientific and full of experience. Mr. Kustel is a veteran mining engineer and metallurgist; while Mr. Riotte seems to be a born mining engineer and metallurgist, whose disciplined and active mind, marvelously deft hands and amazing capacity for work are equal to every demand of the mine, the mill or the laboratory. These gentlemen have associated with Mr. H. Mathey, a mining engineer of varied experience on this coast, and opened a branch of their famous metallurgical works in New York City. The new firm will be an immense acquisition to the mining interests of that city. The character and value of their ores may now be determined by working tests of the ton or fractional parts, instead of the usual and unsatisfactory half ounce, or the costly operation of the 20-stamp mill. We feel assured that their work, in whatever department it may be, will be appreciated in their new field.

IMPROVED PROSPECT IN BELCHER.—The reports that, in the drill hole sent east from the fall of the south drift on the 2760 of Belcher, some good essays had been obtained, having been officially denied, moved the Gold Hill News to remark: The fact is, the Belcher is too well pleased with the hard porphyry out by the drill to want people to deceive themselves as to the exact facts in the case. They have had too much soft vein matter, filled with water, carrying just enough gold and silver to be good for nothing. It shows lack of concentration of the vein—to much spreading out and general diffusion. If the entire amount of precious metal in the lode anywhere from end to end as now shown up on lower levels could be collected into a width of 50 ft. of the vein instead of being scattered through 500 ft., it would make that 50 ft. rich milling ore. Belcher is pleased with the prospect of finding a concentration of the vein when the hard porphyry is passed through; pleased that the eternal floods of the lower regions are not pouring in upon it.

A SEVERE ACCIDENT.—Recently Jas. Doyle, of Vallejo, fell some 30 ft. over a rocky precipice at Eden falls, at Anderson Springs, Lake county, breaking his leg. For a time he lay senseless in the water, and the only wonder is that he did not lose his life. After regaining consciousness he was barely able to raise himself upon the brink of the pool below the falls, where his wife discovered him. He was taken to the hotel at the Springs where he was cared for in the kindest manner, and is now recovering. Mr. Doyle had been camping at the Springs for several weeks and was improving in health before the accident. He wishes us to say that his language is inadequate to fully express the praise and gratitude to the Anderson family for their unselfish kindness to a poor man in his hours of pain and misfortune.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

J. G. COLMARRIN is requested to report to this office from Humboldt Co.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Chew Jackson's Best Sweet Navy Tobacco.

Various Causes—

Advancing years, care, sickness, disappointment, and hereditary predisposition—all operate to turn the hair gray, and either of them inclines it to shed prematurely. AYER'S HAIR VIGOR will restore faded or gray, light or red hair to a rich brown or deep black, as may be desired. It softens and cleanses the scalp, giving it a healthy action. It removes and cures dandruff and humors. By its use falling hair is checked, and a new growth will be produced in all cases where the follicles are not destroyed or the glands decayed. Its effects are beautifully shown on brash, weak, or sickly hair, on which a few applications will produce the gloss and freshness of youth. Harmless and sure in its operation, it is incomparable as a dressing, and is especially valued for the soft luster and richness of tone it imparts. It contains neither oil nor dye, and will not soil or color white cambric; yet it lasts long on the hair, and keeps it fresh and vigorous.

FOR SALE BY ALL DEALERS.

How to STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Eureka Consolidated Mining Company,

Nevada Block, Room 37, S. F., July 15, 1880.

At a meeting of the Board of Directors of the above named Company held this day, Dividend (No. 56) of Fifty cents (50c.) per share was declared, payable on TUESDAY, July 20, 1880. Transfer books closed until Wednesday, 21st.

W. W. TRAYLOR, Secretary.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, Its Formation and History." This
very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing sec-
tions, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & Co., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SLEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

MANUFACTURERS OF

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

Office, No. 230 California Street, - - San Francisco, Cal.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable and simple, is an important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

LEFFEL'S IMPROVED WATER WHEEL. PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 156 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3.00 coin, postage free.

The Explorers' and Assayers' Companion,
(Third edition.) Price of Vol. 1, \$8.

Forwarded (post-paid) from the MINING AND SCIENTIFIC PRESS Office, by DEWEY & CO.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 334 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, sash, Mulay, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

MONEY TO LOAN!

\$500,000

To loan, in one sum or in amounts to suit on Wheat Lands, Wheat in Warehouses, and other good collaterals at current rates of interest.

Savings Bank Books.

The highest price paid for balances in The Savings and Loan (Clay St.), Odd Fellows', Masonic, French, Farmers and Mechanics', by

JOHN T. LITTLE,

302 Montgomery St., rooms 1 and 2, San Francisco.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

DUNHAM, CARRIGAN & CO.,

LIGHTNING SCREW PLATES

WITH TAPS, DIES AND COLLETS COMPLETE.

B, Stock 23 inches long, 7 Taps and Dies Cuts $\frac{1}{4}$ to $\frac{3}{4}$ inch.
C, " 26 " " 7 " " " $\frac{3}{8}$ to 1 "
D, " 53 " " 6 " " " $\frac{1}{2}$ to 1 $\frac{1}{2}$ "

No. 0. Lightning Hand Bolt Cutters and Tappers.

ESPECIALLY FOR CROOKED WORK!

Made to be bolted to the Bench or Table. Fitted with seven sizes, from $\frac{1}{4}$ to $\frac{3}{4}$ inch. Usual assortment, $\frac{1}{4}$, 5-16, $\frac{3}{8}$, 7-16, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{7}{8}$ inch.

VOLUME XLII
Number 6.

How Miners Work in America.

Under this heading the *West Briton* publishes, and other British papers copy, an account of the extraordinary hardships of a miner's life in the United States, as illustrated in the experience of a Cornish miner. At a meeting held recently at West Seton, Mr. John Rule had this to say respecting the kind of a life he led while working as a miner in the State of Nevada. We quote his words as they are printed:

"Some years ago I went to Nevada, and if any fellow wants to know what hard work is, there is the place to go. It is true we earned capital wages of \$4 (16s.) a day, equal to £24 16s. per man per month, but to do so we had to work under so many slave-drivers, and to work like slaves. We had to work 10 long hours every day, and Sundays and Mondays all alike, for there is no Sabbath there kept holy—we had to work on Sundays the same as on week days. All sorts of hardships and privations had to be endured, and the great want of water is one of the greatest. All our allowance of water for everything was one pint per day—drinking, washing, cooking, etc.—no more to be had. You, in Cornwall, who have such an abundant supply of pure water, cannot understand what we had to put up with for the want of a sufficient supply. If you cease working for a moment, the 'bosses' (overseers, captains, or slave-drivers) sing out in a way not to be misunderstood, 'Keep that hammer going.' Of course \$4 or 16s. a day are very high wages, but let me tell you that if a man is getting fair wages at home he had better remain at home, for it almost amounts to selling your life for a few dollars to endure what I did there. There are no humanizing influences in such places—wretched cooking, great exposure, hardships innumerable. I believe, upon my soul, that if men were to work in Cornwall as hard as they work abroad, and he paid at the same rate they are paid at present, they would earn £7 or £8 per man per month. In Nevada it costs to live from £6 to £7 a month, everything there being exceedingly dear. The scarcity of water can be well understood when I tell you that during the whole time I was in Nevada—seven years—we had only rain three times that would sink into the ground as deep as your ankle. If you do not like your work, you can leave it. You can be discharged at an hour's notice, and there are plenty of hands there to take your place."

Mr. Rule's statement will be refreshing news to the large body of miners employed in the various mining camps of Nevada, a large percentage of which is composed of British and Irish miners. And it is safe to assert that the major part of the British miners, at least, came to this country by the advice of friends already here, or that they were allured hither by the large pay and the general good treatment that miners received. Mining, under similar conditions, is alike the world over; and if a difference for the better exists anywhere, it is certainly in the United States. Else why have so many Cornish miners congregated in our mining camps, especially in those of Nevada? It was simply because of the large wages, the relatively easy work, and the fair treatment. We do not believe that any capable or faithful miner, who did his work as well behind the foreman's back as under his eye, would for a moment think of his boss as a 'slave-driver,' or of himself as a 'slave.' If these terms are ever used by miners anywhere on the Pacific coast, it must be among that class that habitually shirks work, and impels the foreman to 'sing out, 'keep that hammer going.' Mr. Rule's experience was peculiar to himself. It is not, and never has been the practice. The absurdity of the charge is shown at once by the rate of wages paid to miners—the substantial sum of \$4 per day. That wage implies either a demand for miners, or the existence of a miner's union, at once powerful enough to fix and maintain a rate of wages, to determine the length of the working shift, and to compel fair and decent treatment. The terms, 'slaves' and 'slave-drivers,' are wholly incongruous with the wage of \$4 a day.

The water famine which existed in Mr. Rule's Nevada camp, where the allowance for everything, drinking, washing, cooking, and even *cetera*, was one pint per day, is perhaps the most

comic feature in his marvelous experience. "During the whole time I was in Nevada, seven years, we had only rain three times that would sink into the ground as deep as your ankle." It is to be hoped that heer was abundant in that phenomenally dry camp. It would have been to the purpose if Mr. Rule had, while making his statement of his mining hardships in Nevada, specified the camp and the region where those horrors existed. It was not on the Comstock—where during the last several years the men have had to contend with the hardship of excessively hot mines, but only for short intervals—for there cool water and ice are supplied without stint. Nor does the condition of any mining camp in Nevada now or heretofore fit the statement of Mr. Rule. And we are forced to regard it as a harmless and extremely dry joke.

The complaint of the want of "humanizing influences," of "no sabbath day kept holy," is the merest puerility. Mines are not found in well-established cities, where the church, and the school-house, and the family and society exist, but in remote, wild, mountain regions. When men go to those regions they carry the

SIZE NO. 2.

SIZE NO. 3.

THE ZIMMERMAN FRUIT AND VEGETABLE DRIERS

good and bad that is in them, and they form the best communities possible under the conditions. As a reasonable man, what else could the Cornish miner expect in the wilds of Nevada, or Australia, or Mexico, or South America? The fact is, that for years the condition of our mining camps has been, under the circumstances, simply admirable. The license which, inevitably attends the wild rush to a new camp soon subsides, and is followed by a degree of order and respect for law which is remarkable. Discomforts there are of course; but on the whole, the fare and the wages and the means of happiness, to say nothing of the opportunities, of the miners on the Pacific coast are, we are justified in asserting, vastly superior to that of a similar class in any part of the world.

SOCORRO ISLAND.—It is stated on the authority of Capt. Delion, of Port Townsend, W. T., who is represented to be well informed respecting the condition of Socorro island, that there was a plenty of water, sea turtles and water cresses on the island when he visited it. It is his judgment that Capt. Jones of the foundered ship *Mathilde* and his party reached Socorro island safely, and after recruiting they probably sailed for the mainland.

OREGON DISCOVERIES.—There are reports prevalent that highly important discoveries of placers and quartz veins have been made in Yamhill Co., Or.; the former in Moore's valley, and the latter on the north fork of the Yamhill river, near Daniel's mills.

RICH MINES IN IDAHO.—The Crown Point and Wolverine mines of the Elmira Co., at Banner, Boise Co., Idaho, constitute a remarkable property. We learn from the *Herald* that in both mines, which adjoin on a common vein, there have been lately developments of a very rich ore body. On the surface the vein varied from 1 to 2 ft. in width, but it gradually increased in size until at the depth of 200 ft. it had expanded to 9 ft. While the vein had increased so enormously in size, the quality of the ore had also greatly improved, and a rich black sulphuret (probably brittle silver ore) largely predominates. Notwithstanding the size of the great vein at the depth of 200 ft. it appears that the maximum width has not yet been reached, for in sinking the shaft only 10 ft. deeper the vein was discovered to be 14 ft. wide, and both walls diverging. It is stated that 1,000 tons of ore taken out of the mine last year produced bullion valued at \$100,000; and further that there is little or no waste rock in the mine. The ore requires to be roasted, and is easily worked up

The Zimmerman Fruit Drier.

We give on this page engravings showing two sizes of the Zimmerman fruit drier, an apparatus which is claimed to be well adapted to the needs of those who wish to turn the surplus fruit of their orchards into a durable and marketable form. We have known of the Zimmerman drier for some time, and have noticed many good notes of its workings in our Eastern exchanges. We trust it may be found well-fitted to California needs, for a small drier for farm-house use is a thing which every fruit-grower desires. The Zimmerman is certainly worth attention and trial.

The editor of the *American Agriculturist* made a practical test of the Zimmerman drier and pronounces in its favor. In the lack of experience of our own with it, we cannot do better than refer briefly to the results described by our contemporary. The *Agriculturist* says: "We stated last month that the 'Zimmerman fruit and vegetable drier' appeared to be constructed upon correct principles. A subsequent trial more than confirms the opinion formed on a mere examination. This drier is made in several sizes; that shown in the engraving is No. 2, and best suited to general use. No. 1 is of half the capacity; No. 3 is of double the capacity, and only needed by those who dry on a large scale. The machine shown as No. 2 is 6 ft. high, 2 ft. deep and 26 inches wide. Below is a furnace or stove for the fuel. This has a door at the front, and the fire is managed without opening the chamber of the drier. In the bottom are dampers to regulate the admission of air, which, entering, is heated by contact with the furnace, then passes among the fruit, etc., and out through a covered chimney at the top thus there is a continuous upward current which, in the larger driers, is increased by so connecting the smoke pipe with the ventilating pipe, that the ascending current from the furnace helps the upward draft. Trays or racks of galvanized wire are provided to hold the fruit, etc., and these rest upon ledges placed at the sides, as shown in the engraving. The affair is readily portable, and may be used out-doors, or inside, where it can be connected with a chimney. Experience proves, what an examination indicated, that this meets every requirement of a useful drier, and it completely obviates all the difficulties that attend the drying of fruit in the open air. The Zimmerman, by allowing the drying to go on in wet weather, prevents the great loss attendant upon the old method, while the exclusion of light, of flies and dust, joined to the rapidity with which drying is done, remove the other obstacles to the best results. This drier turns out a product so superior in appearance, in color and cleanliness as to astonish those who have never seen fruit properly dried, and so unlike the common sun-dried fruit as to warrant the different name that the Zimmerman Drier and Baker Co. have given to the product of their machines, viz: 'Evaporated fruit.' They claim that fruit thus prepared is worth in the market at least double that dried in the ordinary way."

The Zimmerman driers are being introduced on this coast by Linforth, Rice & Co., of 323 Market, St. S. F., and will doubtless be put into actual use with this fall's fruit by many growers.

A CLEVER CONTRIVANCE.—Last year a clever musical contrivance was exhibited in the Sea Beach Palace at Coney Island, N. Y. (which was at that time described in the *Evening Mail*), which consisted of a number of reeds, producing different notes, on the mouths of which stout paper, perforated in such a manner as to produce various airs, was passed, the wind being driven through the pipes by a bellows, and both the bellows and the rolling and unrolling of the strips of perforated paper being worked by a single pedal. This idea has recently been adapted to the needs of perambulating musicians in London, the instrument being carried on a light truck, and the whole affair worked by a single crank, like a band-organ.

GREECE spends more than 5% of her whole revenue in education.

OFFICIAL STATISTICS OF U. S. RAILROADS.—According to the statistics issued under the direction of the Secretary of the Treasury there have been constructed in the United States since 1830, railroads that at the end of 1878 amounted to 81,818 miles of aggregate length. At the end of 1830 there were 23 miles of railroad in the country; at the end of 1878 there were 81,841 miles. The greatest number of miles constructed in any one year was in 1871, when 7,379 miles were added to the railroad system of the country. No year since 1865 has seen less than 1,000 miles built, and no year since 1849, with the exception of 1861, 1862 and 1864, whose contributions were respectively 651 miles, 334 miles and 738 miles. The only year in which more than 3,000 miles have been built were 1856, 3,642 miles; 1869, 4,615 miles; 1870, 6,070 miles; 1871, 7,379 miles; 1872, 5,878 miles; 1873, 4,107 miles.

CRANSTON HYDRAULIC ELEVATOR.—A correspondent at New York asks for information respecting this machine; and if any of our readers who are familiar with its operation on any gravel claim, will take the trouble to give us the result of its working, we will kindly acknowledge the favor.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Silver in the Coast Range.

EDITORS PRESS:—Silver mines in the Coast Range have not heretofore been regarded with great favor I believe, yet here in South Fork (of Clear creek) district, about seven miles from Shasta, seems to be a very promising silver region.

The Chicago mine, situated two miles from Igo, was first opened some 14 years ago, and has been worked at intervals since, yielding a considerable quantity of good ore, a part of which was exported, and a part worked on the spot.

The vein appears to be a true fissure in granite, is somewhat "bunchy," varying in width from a few inches to eight ft. between walls. The pay streak proper reaches a thickness of two ft., consisting of zinclende, antimonial galena, ruby silver, iron and copper pyrites, in a silicious gangue, and carrying from \$20 to \$400 per ton silver. A considerable quantity of gold is found in the croppings, which decreases with depth. The greatest depth yet attained is 215 ft. from the surface, and the last assay of ore from the bottom of shaft gave \$224.51 per ton in silver, no gold.

There is also a large quantity of a feldspathic material which contains as much as \$18 per ton in silver.

It is the intention of the present company to work this good ore here in a small mill now being erected for the purpose, and to reserve the low-grade stuff for future concentration. The mine is very advantageously situated for working, with abundance of timber and water power in the immediate vicinity.

It is something new in my experience to find a silver mine anywhere but in a desert, yet here is a beautiful country where figs, peaches, grapes, pears and other orchard fruits abound, where clear cool water flows constantly from numerous springs, and the banks of the stream are lined with blackberry bushes loaded with fruit. Game is moderately abundant.

In addition to the Chicago are many other silver-bearing veins, which assay well, and some of which give promise of making large mines when opened, as they will doubtless soon be, when the profitable working of the Chicago is again, as it has been before, an accomplished fact, which, it is hoped and expected, will be in about a month from now. C. H. A.

Chicago Mill, July 25, 1880.

North Bonanza, Flowery District.

EDITORS PRESS:—Supplementary to a series of very interesting letters from your Comstock correspondent, a few details relative to the above base metal mine alluded to in my last may not be thought amiss:

There is at present exposed a large and promising ore-body, more particularly on the 400-ft. level, the only point personally inspected. It is not less than 80 ft. in length, six ft. wide in the 300-ft., and 30 ft. or more in the 400-ft., extending down to the 600, where it is said not to be so well concentrated.

The ore carries a large percentage of sulphurets of lead, iron and silver, which sparkle on every hand like so many diamonds in the sunlight, making it as fascinating a sight as the most enthusiastic of miners could well wish to see.

The best ore gives sample assays of \$25 per ton. The concentrations, which have been worked with good results in San Francisco, Salt Lake City and Denver, assay \$100 per ton, from four to five tons of quartz making a ton of sulphurets—the great and only drawback to their successful working here arising from the absence in this immediate vicinity of reduction works suited to such ores.

One most familiar with the ore, and having the largest interest in the stock, thinks that it can be mined, milled and concentrated for less than \$4 per ton, and that some way will in all probability be shortly provided for working the concentrations. He estimates the entire body at from 15,000 to 20,000 tons, and worth from \$15 to \$20 per ton. A. C. K.

Virginia City, July 26, 1880.

Putting on Battery Screens.

EDITORS PRESS:—It is necessary that the wire gauze should be very tightly stretched on the frames. The usual way is to tack one edge down first, and then the gauze is drawn tight with plyers, and tacked to the other side of the frame. I use what I think a better plan. After tacking one edge of the gauze to one side of the frame, the frame is placed almost vertically on the work bench, the side to which the gauze is tacked being uppermost. The loose edge of the gauze, which is generally wider than the frame, is then clamped down to the bench by means of a hatten and nail, and the frame is then forced toward a horizontal position by bearing upon its upper side with the hand. The gauze is thus strained as tightly as it will bear without tearing, and after being tacked to

the frame, is cut loose from the clamp by drawing a knife across it. If the gauze is not wide enough to work in this way from the side of the frame it is drawn from the end. The remaining edges are then drawn in the usual way with plyers, and tacked. In making a frame the sharp edges inside should be rounded off with a rasp to prevent cutting the gauze in use. A further precaution is to tack or glue strips of stout canvass to the frame, including the cross bars; the strips overlapping the edges by a quarter of an inch. Another strip of canvass or blanket is often placed on top of the gauze to make a tight joint with the mortar when the screen is in use. C. H. A.

THE JAMIN ELECTRIC LAMP.—Lately one of the most interesting of the many recent trials of the electric light, says the *Universal Engineer*, took place at the laboratory of the French Electric Lighting Company in Paris, the object being to test the efficiency of the improved apparatus designed by Prof. Jamin. A large and distinguished gathering of ministers and notables connected with science, industry and public works were present on the occasion. After having described his new lamp, and explained its method of working, the inventor proceeded to show, by various experiments, that by its means the following results could be obtained: The whole of the lamps placed on the same circuit may be lighted and extinguished as often as required. Each lamp contains three or more candles, each formed by two rods of carbon 12-100 in. thick, one of which, were it not retained by means of a brass clip, would be pressed back by a spring, so as to interrupt the electric current which forms the arc. When the candle has burnt to the end, the current consumes the brass clip, the carbon rods are separated by the spring, and the arc is transferred to one of the adjoining candles. By this means the light can be kept up for an almost unlimited time. The lighting and relighting of the lamps is effected instantaneously by means of automatic mechanism, and if one of them should by any accident become extinguished, the others are not in any way affected thereby, but continue to burn with undiminished brilliancy. The light, which is well divided, is capable of being regulated at will, from the soft light of a chamber lamp or night light to that of the full power of the lamp. The electric current can be conducted to a distance of 2½ miles from the electric source by means of a copper wire 1.25 of an in. in diameter, and as far as 10 miles by a wire double that thickness. The experiments made at the trial referred to satisfactorily proved the steadiness of the light obtainable with the Jamin lamp. With respect to the cost of working, it was stated by the inventor that each lamp would require only one-half the power which is necessary to maintain the electric candles extending from the Place de l'Opera to the Place du Theater Francais, in Paris, and careful experiments have demonstrated that this system is capable of effecting a saving of one-third, or at least a quarter, as compared with illumination by means of gas. The results of the experiments were eminently satisfactory, and it is proposed to exhibit to public trial a system which seems to promise to solve the important problem of furnishing a really cheap and manageable method of illumination suitable for factories and other large establishments and towns.

A CURIOUS RAILROAD.—One of the most curious railroads in the world is the 10-inch gauge road running from North Billerica, Mass., to Bedford. It was at first hooted at by the people, but the road was completed, making a length of about eight and a half miles. There are 11 bridges on the road, one of which is over 100 ft. long. The rails weigh 25 pounds to the yard. The road is well built and equipped—one grade is 155 ft. The cars and engines will at first eight create wonder and admiration. Their perfect proportions give them a handsome appearance. They are constructed very near the ground, giving them great advantage of safety. The cars have an aisle with one seat on each side, in the same manner as ordinary cars have two seats. The length of the cars allow 30 seats, each person having a seat to himself. The cars are supplied with closets, water tank, are heated by steam and have all the modern improvements. They weigh but four and a half tons, ordinary cars weighing on an average 18 tons. The trains run at the rate of 20 miles an hour with perfect safety. The engine is placed behind the tender, giving it greater adhesion to the track. They weigh eight tons, and draw two passenger and two baggage cars. The cost of the road was about \$4,500 per mile.—*Railway Gazette*.

PLACER MINING ON GOLD CANYON.—At Gold Canyon, a short distance above Dayton, says the *Territorial Enterprise*, may be seen a reminder of some of the primitive mining camps of California. There are two companies of Chinese engaged in placer mining. One of the companies has in operation a water wheel about 10 ft. in diameter, which runs a pump that drains the mine, while the other party keep the water out of their diggings by means of a hand pump, the stroke of which is in accordance with the length of the arm of the Chinaman who happens to be running it. As to how much the ground is paying per man is not known, but the Celestials doubtless have a much better thing than they would were they "railroading it."

Mining in Utah.

According to the Salt Lake *Tribune*, Utah is coming to the front rank in mining. It abounds in more varied minerals than any other known mining country. In every direction we learn of constant developments, and justly speaking Utah produces more bullion than many cracked-up neighboring States. Its solid dividends come honestly out of the ground and are not borrowed from banks to force stock manipulation. Attention is attracted here now by capitalists from the East and West, who will derive good incomes on the investments made. The output of the leading mines is enormous, and mining men visiting this Territory are well satisfied that all that is said of the different mining districts is within bounds.

From Silver Reef on the south to the northern boundary of Idaho and Montana prosperity in mining is visible. To give a correct list of all the paying mines would be simply impossible, as a great many are owned and worked by individuals who care not to gain notoriety.

New life seems to be instilled into Bingham canyon again. The Stewart No. 1 and No. 2 are preparing for active work; the Old Telegraph, Jordan, Yosemite and Tiewauksee are working along and give good accounts of themselves. In the immediate vicinity of these mines are a number of very excellent prospects which will soon come forward as good paying properties. Among those particularly making exceedingly good showing is the Overland in Carr Fork. The out-crop of this mine is traceable for a great distance. Three tunnels have pierced this prominent mountain with a number of winzes and cross cuts exhibiting a great amount of gold-bearing quartz, assaying well. At the north of the canyon an important strike has been made in the Thrush mine, showing sulphurets ore. This claim seems to be an extension of the famous Tiswankee. Several claims at the head of Black Jack gulch are showing up very well and will soon be ranked among the leading producers. Very encouraging accounts come in from Park City, Cottonwood, Alta, Tintic, Frisco, Minersville, Star and Marysvale districts, which deserve extended mention and will hereafter be described.

The Peril of a Miner.

One of those thrilling episodes that occasionally enter into the life of a miner and illustrate its perils, occurred recently in the Wallace and Ferguson mine at Sheep Ranch. The shaft has two compartments, and is 400 ft. deep. Both compartments are used for hoisting purposes, signal bells being utilized to enable the engineer to distinguish between the divisions of the shaft. One day last week three men went down in the bucket, their destination being the 200 level. One of the trio, Thomas Taggart, got into the bucket, while the other two stood on its top and held on by the cable—the "usual way." Arriving at the 200-ft. station the men stepped off into the level, and Taggart had got partly out of the bucket when the hell in the other compartment gave the signal to hoist. The engineer mistook the signal and hoisted in the compartment in which the men had just gone down. Taggart was in the act of getting out of the bucket—had one leg out and one in, in fact—when the latter started up the shaft. The bucket, with Taggart hanging to it, had proceeded but a few feet when it tipped over, precipitating the unfortunate man headlong down the shaft. At the moment of falling—in utter desperation, as a drowning man grasps at a straw—Taggart caught at the rocky wall of the shaft with his hands. By a miracle of good fortune, one of his wrists lodged in a wedge-shaped interstice in the side of the shaft, and Taggart hung by one arm, suspended in mid-air with 200 ft. of space beneath him. No one can have the faintest conception of the unutterable horror of such position. Enveloped in impenetrable darkness, suspended by one arm over an abyss that invited him to certain death if his frail support should give away, and alive to the knowledge that the descending bucket might precipitate such a catastrophe, Taggart's situation was so inexpressibly horrible that its contemplation makes one shudder. Luckily, however, his comrades comprehended the situation of affairs, and by acting promptly prevented a tragic ending of the accident. Taggart was released from his perilous position, escaping any more serious injury than a severe strain of his physical system and mental faculties.—*Calaveras Chronicle*.

A ZOOLOGICAL CURIOSITY.—One of the most curious animals that New Mexico produces is the jnacholote, as it would, perhaps, be called by zoologists, the salamander. The animal abounds in New Mexico, is amphibious, and is generally found in wet places, the hede of creeks, or other such retreats. The creature resembles a lizard strongly, but with the legs and tail of that animal has a fish's body and head, with a tongue which popular superstition erroneously capable of transformation at the will of its owner into a boring instrument more penetrating than a steel gimlet, and which is used to the great suffering of all wood near its habitation. Two long, ear-like appendages are attached to the scaly head, the whole animal presenting as repulsive an appearance as can well be imagined. One of the most valuable ore bodies was discovered in a Grant county mine recently by the boring of a jnacholote that has ever been exposed in New Mexico.

Experiments in Making Diamonds.

It will be fresh in the memory of some of our readers that a few months ago a statement was made to this effect, that diamonds had been artificially produced in Glasgow by a process not yet divulged, and that, having been examined by the highest chemical and mineralogical authorities, the new gems had been found to satisfy all the conditions hitherto alone supplied by the diamonds from nature's own laboratory. When, however, it became known that the new diamonds were almost microscopical, and that a gem worth a few dollars cost 10 times as much to make, the interest in the subject somewhat diminished. It has, however, revived on the publication by Mr. G. B. Hannay, in the recently-issued number of the "Proceedings of the Royal Society," of the precise method by which he obtained his startling and novel results. And if only as a record of indomitable perseverance against ever-increasing difficulties, of scientific acumen, and of the true application of the Baconian method of research, it is worthy of study. Some idea of the nature of the investigation may be obtained from the fact, that out of 80 complex and expensive experiments only three succeeded. Violent explosions were frequent; furnaces were blown to pieces; steel tubes burst, scattering their fragments around. On other occasions, tubes which had been carefully prepared, filled, welded, and nested in a reverberatory furnace for many hours, were found to have leaked, and spoiled the experiment. "The continued strain on the nerves," writes Mr. Hannay, "watching the temperature of the furnace, and in a state of tension in case of an explosion, induces a nervous state, which is extremely weakening, and when the explosion occurs it sometimes shakes one so severely that sickness supervenes."

The diamond-making experiments were started in September, 1879, when Mr. Hannay made many attempts to find a solvent for the alkali metal, sodium, potassium and lithium. But in no instance could such a solvent be found which did not, in the gaseous state and under pressure, unite with the alkali. Even in the case of hydrocarbons, such as paraffine spirit, containing only hydrogen and carbon, the alkali combined with the hydrogen, setting free the carbon. Now, as we know, diamond is pure carbon; hence, when this element was set free from a pure substance, it was thought that conditions of pressure and temperature might eliminate it in the hard crystalline, adamant form, namely, as diamond. Glass tubes were first employed, but, although of great thickness in comparison with their bore, they were found to be insufficiently strong, and they were replaced by wrought-iron tubes 20 inches long by one inch diameter, and having the diameter of the bore half an inch. In these lithium was heated for many hours to a high temperature in paraffine spirits, and on subsequently opening the tube carbon in a hard form was found within it.

Great difficulty was experienced in getting the tubes perfectly air-tight, and eventually the open end was welded, at a white heat, and by that means alone did it resist leakage. Sometimes tubes would burst with an explosion like a gun. A tube 20 inches long by 2½ diameter and ½-inch bore, was filled with a hydrocarbon made from bone oil, to which some charcoal powder was added in order to keep an excess of carbon in the tube. Its open end was welded, and it was heated for 14 hours with lithium. On opening it a quantity of gas appeared, and some minute pieces of hard carbon, which had evidently separated out from solution. Another similar tube burst at the end of eight hours' heating. A tube of cast-iron, no less than 3½ inches diameter, and with a bore of only three-quarters of an inch, exploded at the end of an hour with a fearful report, wrecking the furnace. Several tubes of steel also burst under the enormous pressure, at last shattering the top of the furnace. The author remarks that in nature the temperature must at one time have been much higher than anything we can now produce artificially; while the pressure obtained at a depth of 200 miles below the earth's surface, is greater than that which any of the materials from which we can form vessels can resist. We now come to the great experiment which resulted in the artificial production of veritable diamonds. A tube 20 inches long by four inches diameter, of coiled Lowmoor iron, was bored so as to have an internal diameter of half an inch. The central bore was surrounded by walls of iron 1½ inches thick, and, of course, capable of resisting an enormous pressure. In the tube was placed a mixture of 90% of bone oil and 10% of paraffine spirit, together with 4 grams (about 62 grains) of the metal lithium. The open end of the tube was welded air-tight, and the whole was then heated to redness for 14 hours, and allowed to cool slowly. On opening it a great volume of gas rushed from the tube, and within was found a hard, smooth mass adhering to the sides of the tube. "It was quite black, and was removed with a chisel, and as it appeared to be composed principally of iron and lithium, it was laid aside for analysis. It was pulverizing it in a mortar, when I felt that some parts of the material were extremely hard—not resisting a blow, but hard otherwise. On looking closer I saw that these were most transparent pieces imbedded in the hard matrix, and on triturating them I obtained some free from the black matter. They turned out to be crystalline carbon, exactly like diamond.—*Iron Age*.

MECHANICAL PROGRESS.

Pounding in Steam Engines.

If a steam engine is properly made and erected it should work smoothly and noiselessly in all parts, no matter how high the speed. They do not always work so, and it is evident to the experienced observer that there is something amiss that there is no occasion for which a little search would reveal. If it were only the noise given out by a pounding engine the annoyance would be great enough to call for speedy suppression; but the pounding alluded to is *prima facie* evidence that a loss is entailed somewhere by its existence. The first impulse of an inexperienced engineer, when his engine pounds, is to get a copper hammer and key up the connecting rod, though it did not need this attention at his hands, as it was not the cause of the row. When he finds this does not mend the matter at all, he then keys up the cross head end. In all probability the noise is then just as bad as at first, so he stops and thinks a minute: "It must be the pillow-block; the shaft jumps in it, and that makes the noise," so he screws down the hinder, and sets up the jam-screws in the side shooks. Now he has it all right, so he waits a minute and listens—"tunk, tunk!" It pounds worse than ever; and by this time he has added about 10 horse-power in friction to the load, and still is as far from the source of the trouble as before. What shall he do? If he is a man who knows nothing about his calling, and cares less, he will say, "Something's wrong about the devilish thing, and I'll be darned if I can see where;" but if he is one who feels that for every effect there is a cause, he will not rest until he corrects it, and perhaps it may not be amiss to give him some hints here as to the cause of pounding:

The working parts of most engines in considerable service have been worn more or less out of truth, so that they no longer act as smoothly as when first erected. Crank-pins and shafts of horizontal engines, especially those working at high expansions, are often by no means round: a sixteenth part of an inch is not an uncommon irregularity. They become flat on the sides opposed to the greatest strain from the incoming steam; and when they are in this condition it is useless to keep them up, or run them, until they are re-turned.

Again, the out-board end of the shaft, which is generally carried on a brick foundation, is very apt to drop from the continued strain and jar of duty. This dropping, of course, affects the alignment of the shaft, and throws the crank out of line besides; this twists the connecting rod from one side to the other, and is a very common cause of noise. The remedy for this, it is plain, is to line the engine up again. It sometimes happens with engines that have small clearances in the cylinder that the piston actually strikes one head or the other from the wearing away of the various connections. The remedy for this is either to put in new boxes, or back up the old ones, so as to make the rods of their original length.

By far the most common cause of pounding in engines, however, is in the valve or valves. If there is not enough lead on the valve, it is easy to see that all the lost motion in the various parts is taken up by the fly-wheel on the return stroke, and noise is the result. Keying up will benefit this sometimes, but not entirely; for it is impossible to take up all the lost motion. If there is not enough cushion on the engine (which really amounts to lead in its effects), the same difficulty is observed. The remedy is to reset the valves; and, if the exhaust-passages are not right, to make them so. It is not unusual to find steam engines in use that have been built to sell, not to run; and in these machines there is little or no attempt to produce any economy of working. If they make the fly-wheel go round, it is as much as the purchaser expects. If a good engineer is so unfortunate as to get one of these traps to run, and finds it in bad condition, let him make it as good as he can in his own time, not in his employer's; for, if he stops the engine for any cause, short of a man in the shafting, the employer is very apt to tell him he does not know his business, and hire some one to fill his place.

Very often a steam engine makes a bad exhibition of itself from no particular derangement of great moment, but from a complication of minor ones; a slight want of truth in some parts; a little delay in the valve movement; a weakness in some of the castings that compose it, so that they spring and buckle under strain so much as to throw other parts out of line. The discovery of these troubles and the rectification of them constitute the functions of a good engineer, and the remedies are usually special, not general, so they cannot be set down here.—*American Machinist.*

Speed of Pulleys and Belts.

The *Engineering and Mining Journal* suggests, in answer to a query, that good practice is to run shafts for machine shops at 120 revolutions per minute; wood-turning at 250; cotton and woolen mills at 300 or 400, and then says that at 600 ft. per minute belts on six-inch pulleys lose about two-fifths of their adhesion by centrifugal force. The article recommends pulleys with wooden rims, "properly made," as safer for four-ft. pulleys than cast-iron pulleys,

which ought not to be run over 400 revolutions per minute. It further says that pulleys and belts are more liable to be affected by high velocities than shafts are, the belting losing contact, and the pulleys losing cohesion by reason of the centrifugal force developed by high speeds.

There are plenty of machine shops running shafting at twice 120 revolutions; there are wood-working establishments that run shafts at over 500 revolutions, and as to belts on six-inch pulleys losing two-fifths of their cohesion by centrifugal force, so much depends upon the position of the shafts and the direction of travel of the connecting belts that a general rule like this appears to be lacking in adaptability. Then the weight of belts between points of contact is an element in the problem, and also the absolute weight of belts. Why a wooden-rimmed pulley is safer, running at a high rate of speed, than a cast-iron pulley, does not appear; perhaps the saving clause, "properly made," may modify the statement enough to change its absolute character, but there are probably plenty of concerns in the country which would be willing to insure four-foot cast-iron pulleys of their own make running 1,200 ft. per minute.

Glass Millstones.

We have already made a brief allusion to the introduction of glass millstones into successful use. We have since noticed in the trade and technical papers numerous references to the success that has attended their introduction into Germany. These accounts report recent improvements in their manufacture, which, in connection with the excellency of their work, must bring them into very general notice among millers. The idea of constructing millstones of glass is said to have originated from the observation that the finest flour was produced by those millstones which have the most glassy texture; from this observation came an experiment which demonstrated that pieces of glass, combined in the same way as the French buhr, and similarly grooved on their surfaces, gave better results in grinding than the buhr millstone. The outcome of this successful experiment, we learn from the *Pottery Gazette*, was the invention, by the Messrs. Thorn, of the glass millstones now made by them, and used in Germany with much satisfaction. Respecting their special merits, we learn, on the same authority, that they grind more easily, and do not heat the flour as much, as is the case with the French buhr-stone. In grinding grist they run perfectly cold.

In making these stones the glass is cast in blocks of suitable size and shape, joined with cement in the same way as the French buhrs, dressed and furrow cut with picks, and pointed hammers. It is suggested that the substitution of diamond dressing machines would give better results.

Without going into the technical points respecting the comparative merits of the old and new millstones, which are given at some length, but which would only be appreciated by practical millers, we note simply our contemporary's opinion that, in the event of the success of certain experiments now making on a larger and more important scale than any previous ones, "this discovery will be entitled to rank as one of the most valuable of recent years as regards the milling industry."

FACING SHEET IRON WITH NICKEL.—We reported quite recently the experiments made by Dr. Fleitmann, of Iserlohn, to render nickel malleable. It seems that he has sought an application of his process chiefly by facing sheet iron with nickel. M. Dumas, the eminent French scientist, gives some details in regard to the process. Sheet nickel and sheet iron are welded together under a steam hammer, the product being such that the thin coat of nickel adheres firmly to the sheet iron, and does not separate from it, whether used when cold or when heated. When malleable sheet nickel is heated to a temperature approaching the white heat, in a porcelain retort, and the air in the latter is rarefied by well-known means, all the gases occluded by the nickel are first expelled, the volume being approximated double of that of the metal itself. Then the volatile metals in the nickel are distilled. The nickel remaining behind has not been impaired as regards its ductility and malleability; and M. Dumas comes to the conclusion that the qualities of Dr. Fleitmann's nickel are due to the presence of zinc which he adds. The latter, it would appear, counteracts the influence of the substances dissolved in the nickel, which cannot be removed by ordinary processes of refining.

THE RELATIVE COST OF MOTIVE POWER.—Mr. Bissinger, M. E., at Karlsruhe, Germany, gives the following results as obtained in his examinations of the several motors in regard to the relative cost per horse for each hour. It will be observed that the examination pertained principally to small motors. The relative cost per effective horse-power per hour is as follows:

100-horse power steam engine.....	7.6
2-horse power steam engine.....	44.3
2-horse power Lehmman's calorific engine.....	28.5
2-horse power Hock's motor.....	40.0
2-horse power Otto gas engine.....	26.4
2-horse power Otto Lang gas engine.....	26.4
2-horse power Schmidt's hydraulic motor, supplied with water from the city water works.....	95.00
2-horse power obtained by horses and a gin.....	45.00
2-horse power obtained by manual labor.....	200.00

Otto's gas motor and Lehmman's calorific engine are the cheapest of the small motors, but are, nevertheless, four times as expensive as the 100-horse power steam engine.

SCIENTIFIC PROGRESS.

Pasteur's Important Discovery—Cause of Cholera in Fowls and its Prevention.

We recently made a brief reference to some experiments made by the great French chemist, Pasteur, in regard to "cholera" in fowls. It would be a great mistake to suppose that the subject is one of interest to chicken fanciers only, for M. Pasteur announces a discovery which has much analogy to Jenner's, and which offers a scintilla of hope that cholera, or possibly even yellow fever, may be placed beside small-pox in the list of preventable diseases. M. Pasteur declares that chicken cholera is caused by a microscopic parasite ("le microbe"), and he has studied its habits until he knows what it feeds upon, and can produce it and kill it at will. This parasite, he says, finds its food in the body of the animal, and, therefore, if microbea be introduced therein, so as gradually to exhaust this nourishment thereafter, the animal is proof against the disease, because the microbes die of hunger. The experiment by which he proves his theory is the most interesting part of his discovery. Of 80 healthy fowls, which had never had the disease, 20 died immediately after being inoculated with the cholera poison in a virulent form. The poison was then very much reduced in strength, and a second score of the fowls were inoculated with it. They all suffered from the disease in a slight degree, but they all recovered, and when afterward inoculated with poison of full strength, only 8 of the 20 died. A third lot of 20 was then inoculated twice with the weaker poison, and only five died, when they were afterward tested with the stronger "mixture." The final score of fowls were inoculated four times, at regular intervals, and thereafter it was impossible to give any of them such a dose of microbes as to cause its death. The conditions of the experiment are said to have been such as to leave no room for doubt as to the results obtained. Consequently, it would seem that chicken cholera must be added to the list of diseases prevented by inoculation. It is a long step from cholera in fowls to cholera in man, and M. Pasteur does not seem to take it. He does think, however, that there is a connection between chicken cholera and a disease common among the negroes of Senegal. The symptoms are very much the same, and, in corroboration, it may be mentioned that the cause of the "sleeping sickness" is said to be eating fowls afflicted by a certain throat disease. This hint opens a wide field for speculation. It is more than 80 years since Jenner made scientific use of the vulgar knowledge of the relation between cow-pox and small-pox, between disease in man and disease in brutes. If M. Pasteur's discovery be not itself a second step, it is no slight thing that it shows the path to be still open.

The Nebula in the Pleiades.

Some 20 years ago, Temple, whilst at Venice, discovered, with a four-inch telescope, a fine bright nebula close to the bright star Merope in the Pleiades. It was elliptical in form, and covered an area of nearly a fifth of a square degree. Temple showed it to Valtz and other astronomers, and it was seen by Peters with the eight-inch equatorial of the Altona Observatory.

Subsequently it was looked for by other observers, either without success, or else seen as a very faint, indistinct object. Even Temple, though it is true with another instrument and in another locality, describes it as being far less distinct than when first seen. Subsequently, when observing at Florence with larger instruments, Temple saw the nebula as large and as bright as ever. Prof. Schiaparelli, of Milan, also observed it with the fine refractor at Milan, and describes it as bright and distinct, and completely surrounding the star Merope, whilst outlying portions seemed to extend as far as Electra. Schiaparelli remarks, it is singular that so many persons should have examined the Pleiades without paying attention to this great nebula, which, nevertheless, is so evident an object on a clear sky. Maxwell Hall, in Jamaica, also found the nebula very bright with a four-inch telescope, and shows it as nearly half a square degree in area. Several astronomers came to the conclusion that the nebula was variable. Others even doubted its real existence, and were inclined to ascribe its supposed observation to the effects of atmospheric action. Of late it has been drawn by several observers, so that its real existence cannot be questioned. During this year it has been looked for by Mr. Common with the great 37-inch reflector at Ealing. The nebula was seen as a distinct object of considerable extent, but beyond it, and right within the Pleiades, were discovered two others, both long elliptical nebulas of tolerable well defined form. There seems reason to believe, therefore, that the entire background of the Pleiades is nebulous.

AN EXPLOSIVE ALLOY.—M. Debray, at the last meeting of the French Academy, exhibited an alloy which, when heated, will explode. "A five-franc piece made of it and held near a gas-flame, will detonate, to the astonishment and alarm of the holder." It is composed of one part of rhodium and two or three of lead, heated in a crucible to a high temperature.

Decomposition of Powder in Cartridges.

In the course of some rifle practices lately in France it was found that the older infantry cartridges did not give the ball its normal velocity (which is about 430 meters at 25 meters from the month of the gun for fresh cartridges of the 1874 model). Comparing cartridges of different dates of charge from 1876 to 1880, the velocities were found to decrease with increasing age of the cartridges, down to 415m. for the former year. With this was also observed a diminished precision with the older cartridges. An examination of the weights of powder and ball revealed too small difference from regulation weight to account for the variations in question. M. Pothier then analyzed the matter in the 1876 cartridges, and found them a mixture of carbon, sulphur, saltpetre, sulphide of potassium, sulphate and carbonate of potash, and aescoribonate of ammonia, with some metallic salts arising from a combination of the brass of the case with the constituents of the powder. The numerical results of this and other cartridges clearly proved a progressive decomposition of the powder in the metallic cases. The quantity of powder transformed in a given time depends on the atmospheric influences, and especially moisture, acting at the time of manufacture or during storage. M. Pothier placed in contact with powder of known composition various common metals, copper, iron, tin, lead and zinc, added a little water, and after some time analyzed the powder anew, when it was found to contain new compounds, including salts of the metal and sulphate of potash, also traces of hyposulphite and carbonate of potash. Zinc and (next) copper wrought the greatest transformations; lead, tin and iron were less active. The influence of heat was also studied. When pretty dry powder is put in a zinc or copper case and hermetically sealed heat does not affect it, but if the powder be moist, heat accelerates the transformation.

BEES AND FLOWERS.—A writer in the *Midland Naturalist* says: "Bees, when gathering honey, seem to me (and I make the remark after many observations) to confine themselves during any given excursion to flowers of the same family. Thus, when I have watched a bee or butterfly gathering honey from a rose, I have found that when it next alights it is invariably on another rose, and on no other flower." To this the editor adds the following notes from Kerner: "Flying insects in their search for nectar frequently confine themselves during their rapid visitation of successive flowers to the blossoms of one and the same species. For example, in a meadow at Trins, in the Gschnitz valley, I saw *Bombus montanus* visiting only the inconspicuous flowers of *Anthyllis alpestris*, whilst the numerous and far more striking nectar-bearing flowers of *Pedicularis Jacquinii* and *P. incarnata* were passed over. Contrariwise in another place, in a meadow in the Padal valley, I saw this same species of bee buzzing from one *Pedicularis* flower to another, whilst passing over the intermixed *Anthyllis alpestris*." On this passage Dr. Ogle, the English editor of Kerner's work, remarks that a similar observation as to the habits of bees was made by Aristotle. "A bee," he says, "on any one expedition does not pass from one kind of plant to another, but confines itself to a single species, for instance to violets, and does not change until it has first returned to the hive."

TESTING ALCOHOLIC LIQUORS.—The following hints in regard to alcoholic liquors are given by Dubrunfaut in a French journal: Commercial alcohol and alcoholic drinks differ from each other partially by a characteristic flavor, partially by different chemical properties. A characteristic distinction is the amount of acid in the different liquors. All pure alcohols contain only 1% of acid, while freshly-distilled cognac shows 3%, and this increases considerably when kept long in barrels. In 10 or 12 years the same cognac will have 8% or 9% of acid, while the original percentage of alcohol is reduced from 64½% to 50%. The quantity of alcohol is decreased both by evaporation and the formation of acid. All other alcoholic liquors show the same changes, and in addition also contain copper. The presence of this metal is easily proved by ferrocyanide of potassium or sulphuric acid. If there is only a trace of copper the dry residue is burned and the ash tested. As a rule, industrial alcohol also contains copper. The percentage of acid varies enough to furnish a test for the addition of commercial alcohol to rum, brandy, etc., as an adulteration, or to strengthen it. The copper, however, furnishes no reliable clew.

INFLUENCE OF LIGHT ON SIZE OF LEAVES.—M. Ch. Flahault, in the *Annales des Sciences*, brings forward additional observations to support his view that under equal conditions the leaves of plants of the same species are larger in proportion as we go northwards, these relatively higher dimensions being due to the duration of light of relatively feeble intensity. In cases where the chlorophyll is formed in the absence of light, it must be formed at the expense of the materials stored up in the tissues. The importance of these reservoirs of nutriment is still greater in case of flowers. Thus, in the case of hyacinths, both blue and red, M. Flahault found no difference in the color of the flowers grown in the light or in the dark, the color being manufactured from the stores of material in the bulbs.

The Mining Share Market.

Since our last issue the mining share market has undergone one of the sharpest depressions which has been experienced for months. The depression of shares was sudden, and the reaction immediate. There was no apparent cause for the movement, either downward or upward; but it happened all the same as if it had been decreed, as it doubtless was. Between Monday and Wednesday the advance in several of the Comstock shares ranged from 25% to 75%, and the volume of transactions was large, as for example, there were at least 3,000 shares of Union sold. At the present time the market is strong, and there is a very confident feeling among dealers.

The decided improvement in shares and the strong tone of the market was undoubtedly caused by the news from Virginia City that an important and unlooked-for development of ore had been made in Sierra Nevada. The present indications are that in the work connecting the Union shaft and the 2500 station of the Sierra Nevada incline there are 35 ft. of good ore. The workings have not yet been connected, but both are in ore; the work from the Union shaft has been in ore for 15 ft.

There has also been an improvement in Bodie shares for cause. On the 3d instant news came from that district of a strike in the 600 of the Jupiter mine. This is an interesting occurrence, from the fact that that level of the Jupiter is the lowest point in the district at which ore has been discovered or the working of any mine has reached. The news helped Jupiter to rise easily, and other shares kept him company.

SISKIYOU COUNTY MINES.-A correspondent at Russian creek, Siskiyou county, writes that the quartz mining interest in that part of the county is looking up under the rich discoveries recently made. The strikes were made on the South Salmon river, about three miles from the Black Bear mine. A working test, that is, by mill process, of a fair sample of the ore from a 15-inch ledge-one of the discoveries-yielded at the rate of \$150 in gold per ton; and some of the specimens are enormously rich in gold. Two new 15-stamp mills are to be built-one for the Uncle Sam, a large and rich gold-bearing ledge, and the other for the ledge recently discovered. The mines generally are owned and worked by poor men, and although their mills are small, the merit of their mines enables them to pay their way. One of these days, adds the writer, this camp and others adjoining will do better, and you may expect to hear of our regular shipments of gold bullion.

Bullion Shipments.*

Since our last issue, we have noticed the following bullion shipments:

Northern Belle, July 26, \$9,600; Christy, July 28, \$5,800; Star, July 29, \$3,400; Con. Virginia, July 31, \$48,417.19; Star, July 31, \$2,632; Con. Virginia, Aug. 3, \$51,528. At Salt Lake, July 26 to 31, inclusive-Horn Silver, \$36,500; Ontario, \$42,059.33; Barbee & Walker, \$2,758.36; Christy, \$3,846.95; miscellaneous, \$31,735; total, \$116,899.64. Total shipments for July: Plumas Mining and Water Co., per N. Cadwallader, Pres., \$13,723.03 in gold; Northern Belle, \$118,200; Con. Virginia, \$213,214; Bodie Con., \$28,632; Bulwer, \$8,619; Noonday and North Noonday, \$61,493; Standard, \$145,019; miscellaneous, \$6,900.

*Desiring to make our list of Bullion Shipments as complete as possible, we will be thankful to receive from mining Superintendents and Secretaries notice of all bullion shipments from their respective mines.

CALIFORNIA AND THE CENSUS.-A Washington dispatch to the Chicago Tribune of the 17th says: The idea that California's wealth consists mainly in its gold and silver mines may be dispensed with. A forthcoming statement to be issued by the Census Office will attest that part by showing a difference of several million dollars in the amount of real estate taxable over personal property, the city of San Francisco alone paying nearly one-half. The Census Office is now engaged in preparing tab

DEER SPRING DISTRICT.—We learn from Mr. S. D. Wood-bull, the metallurgist of this district, that work is vigorously prosecuted on the Horton mine. Work was started three days ago in a tunnel following the footwall of the ledge. It is now in a distance of 65 ft. and in a few days the work of crosscutting to prospect the vein will be commenced.

NOTES.—W. A. Greenly is down 20 ft. in a shaft on the Whiteman, an adjoining claim on the same ledge as the Horton. Some rich ore is being taken out. Next week about 2 miles from the Horton. This is a fine strong-looking ledge, the ore from the croppings assaying from \$50 to \$300.

ROUND VALLEY DISTRICT.—It is claimed that an extensive ledge of tin ore, cropping out boldly near the summit of the Sierra and overlooking this valley, is a somewhat late discovery. Still south of this supposed tin mine is another discovery of gold-bearing quartz.

MONO.

LAKE DISTRICT.—Mammoth City Herald, July 24: The measurements of the Mammoth now given are from actual survey, and can be relied upon as exact. In No. 2 tunnel a distance of 32 ft. has been run since last report, giving a total length of 775 ft. A crosscut has been started 222 ft south of the last crosscut on same level. In No. 3 tunnel a distance of 40 ft. has been made; total, 775 ft. A crosscut was started west in this tunnel this morning 204 ft south of the last crosscut on same level. During the week 354 tons of ore have been sent to mill. The ore chutes having been put in thorough repair, by Monday next the company will send from 90 to 100 tons to mill daily.

IF. & M. C. JOINT TUNNEL.—Distance run since last measurement, 20 ft; total length, 921 ft. The new National drilling machine was started on Thursday afternoon, and is working splendidly. Mr. Crittenden showed us to-day a piece of rock from the face of this tunnel. It is a dark, fine-grained quartzite filled with iron pyrites, which drills almost like flint and breaks short. To-day the drill cut seams to beginning to show themselves, and once more the hope of breaking through into softer material is revived.

HOMER DISTRICT.—Mr. Fred Weber, who has just returned from a prospecting trip through Mono, has shown us a sample of ore taken from the Ida Elmore, former district, 6 ft from the surface, that fairly sparkles with gold, and a certificate of assay of ore taken from the croppings runs \$1000 a ton of silver. This ledge is 4 ft wide, with strong and well-defined walls.

NOTES.—*Index*, July 24: Mr. Hawk informs us that he expects shortly to put a force of men to work on the Ontario Nos. 1 and 2. They are very promising locations, situated a short distance southeast of the Homer mine.

BONA VISTA.—Operations are being steadily pushed on this mine. A large ledge on the face of the tunnel came into view of very high-grade ore about 16 inches wide.

LAKE VIEW.—James McDonald is pushing work on this mine. He is taking out some splendid free gold ore, several tons being now on the dump ready for crushing, with plenty more in sight.

LITTLE BLICK.—W. D. Wasson is opening up this mine with a force of 3 men. The Little Bluck lies a little west of the Homer property, and is considered one of the very best mines in the district.

TIOGA DISTRICT.—W. D. Wasson has shown us some good-looking rock from an immature ledge he has discovered in this district, which he located under the name of the Lucky Strike. The ore is a heavy gray sulphuret, carrying considerable iron pyrites, and looks as if it would assay high in silver. Mr. Wasson says the ledge crops out fully 40 ft. in the face of the hill, and is of the size of the piece shown in eight on the surface.

BONN DISTRICT.—*Free Press*, July 30: If a reasonable amount of water could be brought to bear on the placer claims on the east side of the ridge, the owners could realize a handsome return for their labors. As it is, but little water can be secured and then but for a short time during the day. The returns, however, amount to considerable sums, which is quite sufficient for some people these dull times. The patent concentrator in use there is doing good work, it is said.

NEVADA.

SPARRO MINE.—*Transcript*, July 29: This is a recent discovery, and is located on Deer creek, about one-fourth of a mile east of the Providence mine. Two tunnels have been run into the hill, one higher than the other, and a chute from the upper to the lower one connects the two, down which the ore is dumped, and conveyed to the mill, which is near by. A ledge was discovered cropping out on the hillside, which upon running the tunnel a short distance was found to be from 1 to 3 ft thick, which shows well in sulphurets and free gold. A fine body of ochre from 6 inches to a foot thick also encases it between the walls. About 1,000 tons of ore have been uncovered in the two tunnels. A 4-stamp mill, which was completed about four weeks since, run by water power, is kept busy night and day in crushing the rock, which pays from \$20 to \$50 per ton.

FORTUNA MINE.—*Herald*, July 29: Drifting will be commenced in the new shaft of the above mine at the commencement of next week. A 12-ft sump is now being sunk. The rock that has thus far been taken out looks well. Several loads of the same is now being crushed, the result of which will be known in a few days. The ledge grows bigger and looks better on sinking.

LOWELL HILL.—The Morgan gravel mine is employing about 25 men. The company expects to increase the force to about 50 in a couple of weeks. The gravel that is at present being taken out pays from \$2.50 to one-half an ounce to the car load.

DEWEY HILL.—The Dewey mine they have lately returned to gravel. Prospecting is still going on, and will continue to run on the main tunnel. A short time back 80 car loads were run out, and gave a yield of \$775.

OMEGA DISTRICT.—The Tully and Hinds claim, in the above district, is looking well. They are now making their yearly clean-up, and the bedrock is yielding from 2 to 5 bits to the pan.

AS ORE GRAVEL MINE.—*Poathill Tidings*, July 31: The Mammoth blue gravel mine, near Dutch Flat, is a revamped consolidation of 12,000 acres, 1,000 of which is patented land. In old times it sent out \$17,000,000 in dust, one nugget bringing \$5,000 cash.

CONFART.—This mine is working near 50 men and taking out a fine quality of gravel. Much of this is crushed in the mill at the mouth of the tunnel and a long line of sluices are arranged to save the sulphurets and black sand.

CENTENIAL.—This mine has its new shaft finished and the lower levels are expected to be relieved of water in a day or two, when ore extraction will be resumed with much better facilities than heretofore.

JOHN BERRY.—*Transcript*, July 31: John Hussey, of this district, was down yesterday. He reports the water falling in that district. He has cleared the water out in his claims for the season, and appears well satisfied with the result of his season's work. The Birdseye or English claims are still running, although their supply of water is limited. The Hayward or Nevada claims are running with a full head of water.

NEVADA CITY NOTE.—A large quantity of gold dust, from the river canyon, weighing a drift of about 200 ounces, was yesterday brought to the Citizens Bank from one of the gravel mines adjacent to Nevada City.

CROCKER NOTE.—The mines are all working in spite of the heat, which is intense; the thermometer ranging from 90 to over 100 in the shade.

NEW YORK HILL.—*Grass Valley Union*, July 31: At the annual election of the board of directors of the New York Hill was re-elected. They declared an annual dividend of 25 cents per share, payable on the 10th of August, which goes to show that the mine is yielding profitably and the future prospects encouraging.

PLACER.

DUTCH FLAT NOTES.—*Forum*, July 31: All the men are at the mines, at the mills, or otherwise engaged, making preparations for a grand financial harvest. The mines, generally, have never before for years averaged as large returns as at the present time.

LARGE BLASTS.—There was a huge blast set off in the

Polar Star mine on Tuesday, and one in the Southern Cross on Wednesday. These will probably be the last large blasts in these mines this season.

NOTES.—The Rising Star M. Co., of Colfax, paid its first dividend under the new company on the 23d inst., amounting to \$7,500.

MICHIGAN BLUFF NOTE.—*Cor. Placer Herald*, July 31: Our camp has a "lost ledge," "more than half gold," and all the usual incidents of similar stories, and a party has been organized to search for it.

SHASTA.

WHISKYTOWN NOTES.—*Cor. Redding Independent*, July 25: Mining prospects at this place are becoming better every day. Julian & Muchmore have discovered a fine appearing ledge on Whiskey creek, about 2 miles from town. They have sunk 10 ft. on a vein about a foot wide dipping into the hill. The rock will go about \$80 to the ton, and is getting still better as they descend. They intend running a tunnel to tap the ledge about 50 ft from the surface.

A RICH MINER. Mr. Banghart, who undoubtedly has the rich mine of Shasta county, is still working away. His last tunnel is in about 400 ft. He recently ground up 3 tons of rock and earth, which he had previously thrown away as worthless, out of which he got \$37 to the ton. He is now running his astras by horse power, but next summer will put in steam. The wealth of this mine is found in pockets and seams. The present rich streak is a feeder from Old Mad Mule gulch, which in early days was very rich. This mine has been worked for 15 years, and will last a generation to come.

SHASTA NOTES.—This is without doubt the best mining district in the county. Those engaged in mining are making a good living, and a number of them are laying by something for a rainy day. They are shipping from \$5,000 to \$8,000 monthly. Many placer and hydraulic mines are owned and worked by Chinamen. The Church Hill and Dudley hydraulic mines are owned by the Wong Foy Co.

SCORPION.—The Scorpion and the Cold Spring mines have been bonded to San Francisco for six months, for \$12,000, \$2,000 paid down. Notwithstanding the existence of this bond, the owners are still taking out rock and crushing with two astras. The rock will run about \$50 to the ton.

OLD WASHINGTON M. & M. Co.—This mill is running night and day, and is crushing 5 stamps each. The mine is distant from the mill about a mile, the rock being hauled over a passable wagon road. One hundred and thirty tons have been crushed but not cleaned up, and there are 70 tons lying on the dump. A clean-up will be made in about two weeks.

SIERRA.

GOOD HOPE EXTENSION.—*Mountain Messenger*, July 31: Wm. Meserve brought down some very rich rock from the Good Hope Extension; in fact it is the best we have yet seen. He finds good rock as far as Sailor ravine, to which point the ledge is plainly traceable.

BLACK JACK.—We are informed that very rich rock has been struck at this mine at the head of Junior canyon. How extensive the find may be we have no means of knowing.

NOTES.—The Bald Mountain Extension tunnel is making good headway, being in nearly 2,200 ft. Recently considerable water has been encountered, and the builders are growing larger. The American company, Morris-town, will finish cleaning up in about 2 weeks. Morse, of Eureka, will soon return to clean up. Butcher Ranch mine, owned by Jo. Hutchinson, cleaned up \$1,505, after less than 2 months' run. Work is progressing on the Forest Queen ledge, owned by Biber and others.

TRINITY.

CLARKING UP.—*Journal*, July 31: Gold dust is beginning to come in at a lively rate, as miners have commenced cleaning up in several sections. It is probable that this will continue until the end of next month before the operation is completed. The yield in this county the present year will be somewhat in excess of the average. We should be glad to know how much our miners take out, as such information is eagerly sought by parties desirous of investing in the mines of this county.

TULARE.

MINERAL KING NOTES.—*Cor. Times*, July 23: The Empire mill dropped its first stamp this afternoon at half-past 2 o'clock, and prospects are fair for an indefinite continuance.

ITEM.—Mining interests will take a more lively turn soon; all have been waiting for the Empire to start up its mill, and if it makes a good clean-up on the first run, it will give great encouragement to the waiting.

TUOLUMNE.

SONORA NOTE.—*Union Democrat*, July 31: After a 10-day run with 10 stamps, crushing 115 tons of ore from the Confidence mine, a clean-up was made Wednesday. The result was \$7,000 in free gold and 2 tons of sulphurets, which will add materially to the yield. The ore worked came from the recently discovered chute, which promises to be very valuable, bringing the mine back to its former days of prosperity.

NEVADA.

WASHOE DISTRICT.

UNION CON.—*Gold Hill News*, Aug. 4: The drift north and east on the 2500 level, to connect with the station of the Sierra Nevada incline, is making 3 ft per day. It is run without timbering, and to get necessary ventilation. The face is in fair grade ore, which promises well. To meet this drift, one has been started from the incline station, and that is also in streaks of ore.

OTHER.—The drift southwest on the 1000 level has been pushed forward during the past week at the rate of 4 ft per day. Rapid progress is made in the joint Mexican crosscut east on the 2500 level, and in the south drift on the same level.

SIERRA NEVADA.—The raise from the 2300 level for the old shaft progresses well. The north drift, 2400 level, has been stopped for a short time. The 2500 level of the incline has been connected with winze No. 1 of Union.

OVERMAN.—The incline raise above the 700 level is progressing as usual, and the formation carries seams of good looking quartz.

CALIFORNIA.—The slopes on the 1650 level continue to yield as usual, and the ore is of greatly increased value, averaging over \$40 per ton.

BECKER.—The diamond drill is running southwest from the south drift on the 2700 level, but has as yet encountered only soft porphyry and quartz.

CROWN POINT.—Have started east again on the 3000 level, and as soon as the drift is opposite the workings in Belcher, it will be sent south to connect with that mine.

SAYAKO.—Being from the 1300 level to strike at a greater altitude the body of low-grade ore found by the crosscut east. The work progresses well. The bulkheads will be completed during the week, and will be closed on the 2400 and 2300 levels at the same time.

MEXICAN.—The east crosscut on the 2300 level has made 20 ft since last report, and is without particular change of formation. The drain on the 2300 level and in the main lateral drift progresses well.

CON. VINCIN.—From the slopes on the 1750 level the usual amount of ore is taken. The joint Best & Belcher winze, from the 2000 level, is sinking at the usual rate, and the progress in crosscut No. 1 east, and in the drift south on the 2300 level, is good.

YELLOW JACKET.—The east drift on the 2828 level is getting some water, and a strong flow has been struck by the diamond drill on the 2700 level. Work in the sump drift on the 3000 level progresses well.

CHOLLAR.—Water flowing into the C. N. S. shaft still decreasing. It is expected that the bulkheads of the Savage will be closed this week, so that work south toward Potosi can be resumed.

BEXTON CON.—Running north on the 2050 level. The lateral drift is already getting some fine-looking quartz which gives low assays. As the drift is advanced, it will cut further into the vein.

QUINN.—Work confined to the old shaft, the south drift and the drift 40 ft north of the old shaft. The latter is in quartz and clay, the former giving low assays.

ALTA.—Since completing the station on the 2050 level a lateral drift has been started and run south 28 ft. The face is in porphyry carrying considerable water.

LYNN.—Sinking the 3d level, and running east on the 1850 level in hard rock. Work in both places progresses well.

ALPHA.—Cutting soft rock in the north drift, 2810 level, making it necessary to timber the drift; total length, 245 ft.

EXCHANGER.—Cutting a station preparatory to running the diamond drill on the 2600 level in an easterly direction.

AURORA DISTRICT.

THANKSGIVING.—*Emeralds Herald*, July 31: There are now on the dump nearly 300 tons of fair ore, and in sight in the mine are 15,000 tons, estimating 15 ft to the ton. They have run across the ledge 55 ft, but allow for waste 10 ft, which will leave 40 ft of quartz. South drift on the footwall is 55 ft; north drift on footwall 42 ft. South drift on the hanging wall 50 ft; north drift on hanging wall 51 ft; ledge on the surface 80 ft above, about 20 ft thick, which would make a solid mass of quartz 80x80x30, equal to about 18,000 tons. Some 2,244 lbs. an average of the 40 ft of ledge, milled at the miners' mill, went over \$20 per ton.

KRAL DEL MONTE.—During the past week, sinking the main shaft has been steadily carried on, the distance sunk averaging about 3 ft per day. The total depth is now 630 ft. The formation is changing rapidly, and is of a very kindly character, being much more solid than heretofore. Some very promising strata of quartz are now making in the bottom of the shaft.

GRAND TRUNK.—The east drift has been extended about 30 ft during the week, and broke into the ledge last night. The ledge in this drift appears much stronger than on the surface, although they have not cut into it far enough at this writing to tell much about the value of it.

ONTARIO.—This shaft is now about 25 ft deep. The ledge in the bottom is looking much better than at any other point, and in some places carrying a good deal of mineral.

BRISTOL DISTRICT.

HILLSIDE.—*Pioche Record*, July 24: The Hillside furnace is running out a good deal of bullion, which is accumulating on the dump awaiting shipment, but the amount will be somewhat lessened upon the starting up of the cupel furnaces, which are to commence refining bullion to-morrow.

MEXICIA.—In the drift on the 125 level of this mine, running east from the whim shaft to connect with the old workings, a body of unusually high grade ore was encountered, which, upon appearance, will ultimately lead to an important development.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, July 31: The mine is looking better since our last report. The air drift being now completed, the work of thoroughly prospecting the 4th level will be pushed. The intermediate, between the 3d and 4th level, crosscut has been run in which 4 ft of ore have been struck. The ore gives good average assays. Only 2 days work has been done at this point, but the showing is very favorable.

GENERAL JACKSON.—The incline is now down 185 ft. The crosscut south from the 150 level is again being pushed, work having been discontinued on it some time ago on account of foul air. The ground is looking more favorable than ever, and when the connection shall have been made between the 2 inclines, rapid progress will again be made.

VICTOR.—The main tunnel has been advanced this week a distance of 9 ft. The formation is improving and getting softer.

MORO.—The shaft is down about 30 ft. The ore is very rich, assaying \$30 per ton. The mine will be developed by the owners as far as possible.

MOUNT DIABLO.—Work all through the mine has progressed this week steadily and satisfactorily. The slopes are looking well and producing very fine ore.

CHERRY CREEK DISTRICT.

EL CAPITAN MINE.—*Cor. White Pine News*, July 25: Work on this mine at Silverburg is pushed forward with energy in their lower tunnel. They are working 3 shifts, and expect to cut the ledge in about 6 weeks. The mine is now on the right track. During the past few days they have made a test by working their ore by dry crushing instead of wet, as they formerly have been doing, and the result is most satisfactory. The company will either remodel the old mill into a dry crusher or build a new one.

EUREKA DISTRICT.

RICMOND.—*Louden Mining Journal*, July 10: The usual telegram from the mines at Eureka, Nev., states that the week's run was \$70,000 from 1,100 tons of ore. During the week the refinery produced four bars to the value of \$54,000.

RUBY-DONNERBERG.—The report states that the company's operations are vigorously prosecuted, and the returns are of a highly satisfactory nature, having regard to the fact that development rather than to large ore raisings are considered.

EUREKA TUNNEL.—*Sentinel*, July 25: This tunnel is now in about 1,400 ft, and has a perpendicular depth from the surface of 800 ft. The shale belt has been passed through and the face is in mineral-bearing lime, highly impregnated with chlorides and other evidences of the near proximity of an ore body.

SECRET CANYON.—The Geddes & Bertrand mine, in Secret canyon, has shipped over 30 tons of ore to the Richmond works during the past 10 days.

PHILADELPHIA DISTRICT.

BELMONT.—*Cor. Courier*, July 24: We are extracting ore in the slope and crosscut above the 300 level and north end of the mine, also opening up 20 ft above the 300 level north and south from the upraise, which is looking very promising and producing some very fine ore.

BARRELORE.—Since my letter of July 15th, we have advanced 0 ft in north level, which continues to look well. Five assays made yesterday, from dump, gave \$197.72 to \$1,400 in silver; not tested for gold; ledge 6 ft. North upraise progressing well. The ledge is looking better, and as we advance, the prospects are very flattering indeed. We have a large quantity of ore on dumps awaiting reduction work.

NOTE.—Rich ruby ore is being found in the Morey District company's mine. The work of development is being pushed vigorously. The mill is kept running steadily on ore from the mines, and the bullion shipments are regular.

PARADISE DISTRICT.

OHIO MINE.—*Cor. Reporter*, July 24: Ten tons of ore from the Ohio mine were received at the 300 level during the week, and the consignments of like quantity is on the way; when it arrives the whole will be worked, and if the returns are as good as received by the company from Salt Lake, they will enter into permanent arrangements with the Bullion company for working all ores from the Ohio mine.

PIOCHE DISTRICT.

EL DORADO CANYON.—*Record*, July 24: The new discoveries down near El Dorado canyon are developing grandly, and are said to be immense. Prospect holes on the ledge show it to contain large amounts of ruby silver. One shaft has been sunk to the depth of 40 ft, and the ore for the whole depth is filled with ruby silver.

DAY DRIFT.—The winze in east drift, on 300 level, advanced 7 ft last week; total, 23 ft; bottom in spar and ledge matter, with bunches of ore. Sinking on spar and ore on 400 level; cut large open fissure. The southwest drift on 400 level has been extended 12 ft; total length of drift, 95 ft.

WARD DISTRICT.

MARTIN WHITE.—*White Pine News*, July 24: We learn from parties just in from Ward that ore has been struck in the Martin White main tunnel, but how much of a strike is not known at present. It cannot possibly be the ore

body the tunnel is headed for; that would be expecting too much. The main ore body may be reached in the next 2 months.

ARIZONA.

GLOBE DISTRICT.—*Silver Belt*, July 24: The richest ore in the winze of the Black Morris, at a depth of 150 ft, is 4 ft wide. Four tons of ore taken from the entire width of the vein, and milled by wet amalgamation as a test, and worked to 90% of its pulp value, gave \$330 per ton.

TOWNSHIP.—Development on this mine is being pushed as rapidly as possible, with good results; every opening showing a fine body of ore. There is enough ore in sight to keep the mill running 12 months.

SYLVANUS, No. 1.—Four assays of ore, taken from as many places on the crosscut of the Sylvanus No. 1, with a view of determining the value of the vein, averaged \$57.34—a good showing for so large a body of free-milling ore.

RICHMOND BASIN NOTES.—Mr. L. A. Vall has just returned from Richmond basin, and has shown us some very fine specimens of ore from the Marcano and Dundee mines. If reports are true, these are some of the finest prospects, for amount of work done, in the basin. Mr. Bruce of Richmond basin, brings news of a rich strike in the La Plata mine.

PATAONIA DISTRICT.—*Cor. Citizen*, July 17: The mountain, which gives the camp its name, together with the foothills, is so bewilderingly covered with mineral deposits, and these surface deposits have such an enormous extent, that one is soon at a loss to doubt as to whether the mineral or the country rock has the preponderance.

HOLLAND MINE.—The singular feature of work at all the claims here is the fact that it is not necessary to extract a pound of waste, and at the Holland I saw on the dump 500 tons of ore, and not a particle of waste dump. The developments on the Holland consist mainly of a 65-ft shaft, at the bottom of which is a 25-ft crosscut, every inch of which is in ore.

COLORADO.

SUNNIT COUNTY.—*Cor. Boulder News and Courier*, July 21: Within 2 years fissure veins and contact deposits have been discovered at various points, and now, at Kokomo, Carbonateville, Red Cliff, Conger's camp, Lincoln, Breckenridge, Swan City, Frisco, The Snake, Montezuma, Chihuahua, Decatur, prospecting is lively, and a great many mines are being developed. At Kokomo there are 3 smelters; at Red Cliff, 1; at Breckenridge, 3; at Larimer, 1; at Lincoln City, 1; at Montezuma, 1; and at Chihuahua, 1. About half of these are in operation, and the remainder are so nearly ready that 2 months will see them in full blast. This will give a home market to all kinds of ores, and enable low-grade mines to be worked to good advantage. The ore in the county is carbonates in many places, chlorides, galena of all grades, gold-bearing quartz and sulphurets of all varieties.

CHERRY CREEK DISTRICT.—*Register*, July 23: The well-developed Kent ledge, in Nevada district, is showing up much better in the 700 level than in the upper workings. A fine body of smelter ore has been recently encountered west of the main shaft, which is continuous up to the 300 level. Free gold specimens have been found.

IDAHO.

WOOD RIVER NOTES.—*Yankee Fork Herald*, July 24: Parties just from Galena say there are about 1,500 men in the Wood River and Saw Tooth districts, the greater part of them either prospecting or developing mines. Some very good strikes have been made this season, and nearly all the boys from this section are in possession of mining property. The mines in the different districts are opening up well. The general reports from Wood River are that the mines are many and rich, and that when smelters are once established there it will make a country hardly second to the carbonate camp of Colorado.

LOST RIVER NOTE.—New and very rich silver mines are reported to have been struck on Lost river, about half way between Kennedy's and Antelope creek, and about 60 miles from Blackfoot.

BAY HORSE DISTRICT.—The Custer company and the two smelting companies in Bay Horse districts are now giving employment to the idle labor of these two districts, so that with other works and improvements going on there is work now for every man here who wishes it.

BONANZA CITY ITEMS.—The ore sacked for shipment in the Badger mine the past winter is worth from \$700 to \$800 per ton. It will probably go out to the Bay Horse reduction works for treatment. The mine is looking well, and the Badger can be set down as one of the numerous profitable veins of the district. James A. McFadden has reached a vein of high grade ore in the Fraction, the eastern extension of the Montana mine. The tunnel at a distance of about 100 ft passed through a large body of medium and low grade ore, and a few ft beyond this the true vein, containing several ft of very fine gold and silver ore, was struck.

BOISE COUNTY NOTES.—*Idaho World*, July 27: The Chinese companies drifting in Gold hill, on the Bear River side, have cleaned up the dirt taken out during the past year, and have commenced refilling their dumps. One of these companies employs 30 men the year round.

FLOWMAN'S CLAIM.—The work of cleaning-up commenced in this claim, on Bear Run, last Friday. The indications are favorable for a good yield. This claim was worked by a Chinese company, who leased it last spring. Work will be continued on Mr. Flowman's hill claim as long as water lasts.

ITEMS.—Keane & Hall will not clean-up for some time yet, being unable to get water for that purpose at present. They will continue drifting with their usual force. Three claims, owned by the Bueno Vista Bar Co., are still running on the west side of Elk creek, opposite the city. The water is being used to reduce the ore from the Atlantis alone. A great many other mines are being discovered. Thomas Lowe on Saturday says he saw a man take out 10 tons of ore from a claim near the new discovery of Avery and party, which will average not less than \$300 to the ton.

DEER LODGE COUNTY.—*Butte Miner*, July 27: On the Bear mine a force of 20 men continue the development. From the bottom of the middle shaft the east drift has been extended to a length of 45 ft on the hanging wall side of the ledge. A breast of ore 6 ft wide is being extracted, the bulk of which shows a profusion of native silver, and with it 50% of copper, which of course pays handsomely for shipping. The west drift is in 35 ft, the face being in ore of excellent quality.

HOT SPRING.—There is nothing new to report from this mine except that work on the west shaft has been stopped to await the erection of a whim, as a windlass cannot hoist the ore even as fast as one man can knock it down. The stopes from the west level are looking well and are producing as usual from 12 to 15 tons of ore daily.

DIAMOND.—The shaft which has been excellently timbered in down 83 ft in a body of ore which extends from one side of the shaft to the other with occasional bunches of porphyry. Only 3 men are employed, who extract 6 tons of ore per diem, assaying in the neighborhood of \$30. As the owners of the mine also own a mill, this comparatively low-grade ore can be profitably reduced,

The Mineral Resources of Washington Territory.

No. 1.

A SERIES OF ARTICLES PREPARED FOR THE MINING AND SCIENTIFIC PRESS BY OUR RESIDENT CORRESPONDENT, ELDEIDGE MORSE.

THE SKAGIT GOLD MINES.

The world knows all about the golden wealth found in the streams and mountains of California. Thousands have penetrated to the most inaccessible parts of British Columbia, and have visited the shores and mountains of far northern Alaska in search of the precious metals; but this is the first season that the general attention of the Pacific coast has been directed to Puget sound as a center of mining enterprise, or to the Cascade mountains in Washington Territory as depositories of mineral wealth in gold and silver, in quantities sufficient to compare with its neighbors to the northward or to the southward. None could give any good reason why these precious metals should not be found in these mountains in quantities as great as they have been produced to the northward and to the southward, in each prolongation of the same system of mountains, except that all previous efforts had to a certain extent been unsuccessful. No large quartz mines had been opened up, and no extensive placers, until recently, been struck.

These things have most undoubtedly produced a tendency to sneer at the possibility of ever finding mines as rich in Washington Territory as have been found in California, Nevada or British Columbia. Still, within the past few years, both placer and quartz mines have been found that promise to equal those in British Columbia and Alaska, and possibly to compare favorably with those of California and Nevada. A wide gold-bearing belt undoubtedly exists, crossing the Territory from north to south, the limits of which may be described in subsequent articles. In this number an attempt will be made to give a concise outline of what is already known in reference to

The Mines on the Skagit River.

Like every other river flowing into Puget sound, fine float gold can be found the whole length of the Skagit. In some places the deposits are rich enough to afford small wages to those who are willing to work them.

In 1860 an Indian woman picked up a nugget of gold near the mouth of the Sauk, some 60 miles up the Skagit, which she sold to the Puget mill company at Port Gamble for \$27.

Ever since that time every little while attention would be called to coarse gold brought from the Skagit by the Indians; but prior to 1878 no specimens of coarse gold had been found by white men on that river or its tributaries; at least no report of such finding has ever been made public. Had anyone found coarse gold, the public by this time would have heard of it.

Prospecting that led to the present excitement began in 1877. From five to seven men were at work during the summer and fall of 1877 prospecting the Skagit and its tributaries, finding in many places good prospects of fine gold on the surface, but failing to discover coarse gold. Prospecting was resumed in February, 1878, when a party went nearly up to what is now called Ruby creek. All but two of the party stopped at the Tunnel canyon, some six miles below the creek. The two who went on—John Rowley and John Sutter—struck coarse gold about two miles up Ruby creek. They found in one pan one dollar and a half. They found so many small rubies in the black sand that they named the stream Ruby creek at that time. Then, prospecting up the Ruby, they struck coarse gold in several places. This stream is about eight miles long, and is formed by the union of two streams, since named Granite and Canyon creeks. These men prospected up both of these, but found prospects only on Canyon. They then prospected on Skagit, above the mouth of the Ruby, and found plenty of fine gold, but no coarse. On returning to the Tunnel canyon, another party was met coming up. In June, 1878, of this second party, Rowley, Conn, Duncan and Presentine went up the Skagit, ten miles above the mouth of the Ruby, and failed in trying to cross the mountains into Ruby and the head of Canyon creeks; then they came down to the mouth of Ruby and went up that stream. They panned out some \$15 worth of coarse gold near its mouth. They also found coarse gold up Ruby and Canyon creeks, but were compelled to return for provisions. A freshet came on while their supplies were near the head of canoe navigation, some 16 or 18 miles below Ruby. The freshet had carried off their canoe, leaving them on one side and their supplies on the other, and the river was too high to attempt crossing, and they had to travel nearly three days without food. In September, 1878, Rowley and Presentine were on Ruby again. They found bare bedrock on Canyon creek, and in one day took out \$20.

Having no provisions, tools, etc., they struck out for supplies, and met Sanger, Woods, and Armstrong at the Tunnel House, and again went up Canyon creek, where, in two hours,

the five took out some \$45. They obtained some \$68 in all that day. In November, 1878, Messrs. Rowley, Armstrong, Woods, Pierce, and Casey went in and wintered on Ruby. Cold weather and deep snow prevented them from accomplishing anything to speak of. But in February, 1879, they organized Ruby mining district. Representation day was fixed at July 1, 1879, on which day there were 29 men there; but high water, lack of tools, and other difficulties prevented them from accomplishing anything for a couple of months, and so discouraged the men that half of them were about leaving in disgust. On the last Saturday in August, 1879, several of the party were encamped about two miles below the head of Ruby, having left Canyon creek, on their way out. One of them, Barney McCort, took his pan and crossed the creek. In 20 minutes he took out some two dollars. Five others soon joined him, and that evening they took out \$22. These six men stopped there and formed the Nip and Tuck company, which took out nearly \$800 in six weeks. Then one or two of the company stopped after the rest left for the season, and took out enough more, so it is estimated, to make \$1,000 earned by that company of six men last fall.

Rowley and Presentine, with four others, tried for two months, unsuccessfully, to work the Discovery claim, on Canyon creek. They left about the 1st of September, 1879. When going out they met Sanger and Duncan, and gave them authority to clean up their cut, etc. Armstrong joined them. The three cleaned up \$283 from the abandoned cut and bedrock in a few weeks. In not over six weeks, during last September and October, some \$3,000 was taken out by these three miners. Perhaps as much as \$4,000 in all was taken out last fall. About 60 men in all visited the mines that season; but not over 25 did any work to speak of. The gold taken out last fall was what created the great excitement last winter, and caused the rush to that locality over the snow, until, at the present time, some 1,200 men have visited the mines, over one-half of which number have taken up claims. What the present outlook is will be best understood by

A Brief Description of the Skagit River

And that section of country. This river is about 175 miles long. It rises in British Columbia, not far from the Fraser. One of its tributaries rises within 14 miles of Fort Hope. About 10 miles north of the line the west fork joins it; then for 30 miles the stream flows nearly south to the mouth of Ruby, and except for the jams, the river is navigable for canoes all this distance. For this distance the river bottoms are three miles wide, with timber, climate, etc., like those found on the eastern slope of the Cascade mountains. This is a very peculiar valley, with high mountains each side of it. Mount Baker lies just west of it, 10,000 ft. high; while the main range of the Cascades, from 6,000 to 7,000 ft. high, is just east of it. About half way between the mouth of Ruby and the British line is Lightning creek, which, like Ruby, flows into the Skagit from the east. The tributaries on the west are Eagle creek and Beaver creek. The development of the mines will cause this mountain valley to be settled by hundreds of families, who will grow produce for the mines.

Below the mouth of Ruby the Skagit is a terrible river for some 16 or 18 miles until Goodell's, the head of canoe navigation, is reached. It is but little more than a series of wild cascades, flowing through a succession of very deep and narrow canyons. One of these, some six miles below Ruby, is called Tunnel canyon.

A Remarkable Canyon.

Here also comes in from the east Thunder creek, through a canyon two miles long and 250 ft. deep, and so narrow on top that a man can almost step across it. The creek is nearly 40 ft. wide. In flowing through this canyon it makes a noise like rolling thunder. Its mouth is near the upper end of Tunnel canyon. Here the river was exposed to flow under ground for nearly a mile, and the first prospectors there described it as an "underground tunnel." From above, below and each side it has that appearance. It is only by going to the edge and looking down two or three hundred ft. into the narrow and deep chasm which yawns beneath you that the mistake is discovered. Ruby also flows into the Skagit through a very narrow canyon. For some six or seven miles below Goodell's, although navigable for canoes, the river is very swift and wild, large boulders (in the center of the stream and some bad riffles; then comes the portage, where the boulders are so thick and the fall so great that none but the most skillful can or dare shoot through. In times of high water the waves roll over the boulders from six to 10 ft. high. In very low water the waves may not roll over two or three ft. high, but the boulders are so much thicker on the surface of the water that the dangers are nearly as great. The worst part of this portage is only some 300 yards long, but there are very bad riffles just below the main portage. It was in these riffles six men were drowned on the second of May, 1880. Canoes and batteaux usually are taken through this place with a line, while the freight is all packed around it. In going down only a small portion try to shoot through. Then, no matter what is the skill, a miststroke will consign the whole outfit to a watery grave. At the time of the accident above referred to, the passengers walked around the portage, while the two in charge, Dave Ball and an Indian, shot through all right; then above the lower riffles they took in the 10 passengers; the canoe was fit to carry

six; she swamped; Ball was drowned and five passengers with him; the others were saved by a passing boat. Had this canoe a smaller load, or had the passengers walked 300 yards further, all would probably have got down safely.

Below the portage the country grows gradually smoother, the river easier to navigate, and it is but a short distance to where the valleys are wide enough to cultivate. The branch of the Cascades, of which Mount Baker is the highest peak, may be said to cross the Skagit river at the portage, which is a very narrow canyon, cut across very high mountains, through which the river flows.

Portage City.

Three miles below the portage is Portage City, the supposed head of steamboat navigation. Most of the year steamboats of sufficient power can reach here, although none have gone farther than the mouth of the Sauk, 20 miles below. From Portage City there are no real obstacles to canoe navigation but what can be surmounted by hard work; the riffles are, some of them, swift, but not dangerous to skillful canoe men. The Sauk is the present head of agricultural settlements. Here is a beautiful tract of very fertile land, where there is enough vacant to make homes for hundreds of families. Doubtless it will all be occupied before long.

Eight miles below the Sauk, the Baker river flows into it from the north. It drains the southern slope of Mount Baker. Fourteen miles below Baker are

The Skagit Coal Mines.

The mine is called the Cumberland, on account of the forging qualities of this coal, and its resemblance to the celebrated Cumberland coal. Some seven or eight miles above these mines, the fertile low lands of the Skagit are 10 miles wide, with only a few settlers on the river bank. It is about 16 miles from the coal mines to Sterling, which is quite a logging center, and 10 miles from there to Mount Vernon, which is 12 miles from the sound. Mount Vernon is one of the best known points on the river, and the usual stopping place for sound steamers, and where most of the miners start in canoes to go up the river. It is expected that after another month or so travel will be sufficient to induce steamers to go regularly as far up as the Sauk, and perhaps to Portage City. The country around the mouth of Skagit is considered the most productive in western Washington.

The Snowfall.

Last winter snow fell the heaviest in the mountains and on the sound ever known since the Hudson Bay Company first were here. The forepart of January, in a single week, snow fell over four ft. deep at Seattle and other points on the sound. In the open places, near salt water, it melted nearly as fast as it came; but in the timber back from the water, and in the mountains, it fell much heavier and did not melt. The 1st of March, 1880, the snow probably averaged 10 ft. deep in the mountains. This deep snow commenced falling about the same time as the rush to Ruby creek began last winter. It caught a large number on their way in, just above Goodell. The soft snow was so deep and snow slides so frequent that the first party who broke the trail were 12 days going some 16 miles. After the trail was well broke, a man would carry 80 lbs. and go in in one and one-half days. The troubles of the first lot discouraged some others, so they concluded to try to come in via Fort Hope. There was a wagon road 14 miles from Fort Hope to where it struck the Skagit, thence seven miles farther down it, and an Indian trail to where the two forks joined (at a place named the Steamboat landing) at the head of the upper valley of Skagit, 10 miles from the boundary and 30 miles above Ruby. Here they were to come down on rafts and a-foot along the bottoms. There are no obstacles to a summer pack trail on this route, but the terrible snowstorms of the past winter were so difficult to overcome that the men who came in that way were from 17 to 42 days on the trip. The average was about 30 days. All went out via Goodells and down the Skagit. Some 50 or 60 came in via Fort Hope.

The water in the Skagit river is highest in early summer and lowest in winter. On the tributary streams in the mountains, the melting of the snow makes high water oftentimes until late in summer, and low water during the fall and winter.

Ruby Creek

Is about 40 ft. wide, swift and with many boulders in the channel; three miles of it runs through a canyon so narrow it can be worked only by fluming. At extreme low water it contains about 7,000 miner's inches of water, flowing under one-ft. head. A flume made so the claims there could be worked eight months out of the year, would have to be large enough to carry some four times that amount of water. Winter is the best time to work most of the claims, on Ruby creek, if they are only first opened in the fall.

Canyon and Granite Creeks

Are each nearly one-half the size of Ruby. The past season gold was first discovered on Granite creek, of quality and in quantities sufficient to induce men to take it up. There is very little float gold on Granite. Canyon creek is some 15 miles long. Its chief tributaries are Mill, State and Gatten's creeks. All of Ruby is supposed to be taken, 10 miles of Canyon, about 8 of Granite, State and Mill creeks, while a number on Gatten's, Cedar and other small creeks, are also claimed. Near the mouth of Ruby, in several places, gold similar to that in the bed of the creeks has been found in the

mountains several hundred feet above the head of the creek. Something over \$100 has been washed with snow water there this spring. About \$200 has been also taken out near the mouth of the creek this spring with pan and rocker.

There is a separate mining district for Ruby, Canyon and Granite creeks. Besides these three, another district called Enreka district exists, embracing Lightning creek and its tributaries, where excellent prospects are supposed to have been found on one of its branches, formerly called Three Fools' creek, but now named Eureka creek. Some 40 claims are taken in that district.

About 70 claims are taken on Thunder creek, where is also another district.

This is a very wild and exceedingly rough country, in the most inaccessible part of the Cascade mountains. The gold is similar to Caribou gold in quantity, quality and location; it is quite coarse, but thus far no nuggets above eight dollars in value have been found. No gold to speak of, besides float gold, has been found except on or near bedrock. This has been reached in but few places, and wherever reached the pay has been well distributed and abundant. In Feb., 1878, no snow was on Ruby creek. In the winter following, snow was not at any one time over three or four ft. deep. Last winter set at fault all previous calculations. Men could have worked most all of Ruby, had they had grub and tools in, and claims opened out last fall, all of last winter, despite the big snow; but in the smaller creeks, where the canyons are narrower, the avalanches have filled the canyons from bank to bank with snow from 20 to 150, if not to 200 ft. deep. In many places it has brought down masses of timber, rocks and earth that will be very difficult of removal. The writer traveled for several days over streams that were hidden from sight by snow drifted in, or carried by avalanches, so that for miles at a time the stream would be invisible. There are some of these small streams that poor men could work profitably, if it were not for these avalanches. As it is, about one dozen companies will be almost certain to make money this year, others will make expenses, and others, the greater number, will make little or nothing. With but few exceptions, so far as discovered, these are not poor men's mines. There is, undoubtedly, plenty of gold on the bedrock that will pay to get it out; but it requires capital and experience to handle it. The chief benefit of these mines to poor men will be the sale of claims to strong companies, and what they may make working for wages for these companies two or three years from now, after the mines are well opened. It will probably take a term of years to wash them out. This year they will do well if they finish prospecting, get in good pack trails, and a few take out money that will fairly represent the mines by next September. But little gold can be taken out before August. A trail for pack animals will be put in from Fort Hope, and Seattle merchants, etc., will probably put in another near the present foot trail from Goodells. Another trail may cross from Granite creek to Cascade river, the stream flows into the Skagit four miles below Portage City. A pony trail used by Indians goes over the mountains from its mouth. This trail to it from the mines will furnish an outlet to the east of the mountains, as well as to navigable waters on the Skagit river.

An Overworked People.

At a recent meeting of American physicians and surgeons, William Walter Phelps made the following remarks, which will bear careful and repeated reading: We are a nation without contentment, without rest, without happiness. In a feverish race we pass from the cradle to the grave—successful men, to whom life is a failure. Our boys leave the university when English boys leave their school. Our merchants leave their trade, retiring to some more dignified or honorable work, as they believe it, at an age when the German merchant first feels the master of his trade. We are always anticipating the future, forcing the task of a whole life into part. Worse, we are not content with doing a year's work in a month in our calling, but we must do enough in all other callings to win distinction there. In other lands it is enough to be a lawyer, physician, clergyman, merchant. Here we are nobodies unless we fill the sphere of all human occupations. One must be a statesman and know political science as if already in office. He must be an orator, and ready to persuade and instruct; a wit to shine at the dinner table, a *littérateur*, a critic! There is too much human nature in man for this to mean anything except a discontented life and a premature death. And the remedy? Correct public opinion. We must honor the man who faithfully does his task, whatever it is. Not the task, but the faithfulness with which it is done, must be the measure of the honor. Then men will be content with their father's trade. This will give us that family association which is a sure pledge of good conduct and patriotic love. This will give us, too, that traditional aptitude which alone gives great mechanical excellence. It will not be a bad time for American manufactures when we find stamped on them what Mr. Griggs finds on Japanese bronzes, "Done by the ninth bronzer in this family." Then men will keep the occupation of their youth for their age, and, having leisure, will build the foundations broad enough to withstand bankruptcy. Then men will seek excellence in their callings. Then men will alternate labor with rest, and obey the demand of nature,

THE ENGINEER.

Another Great Engineering Work Completed.

An English exchange gives us the following account of the completion of one of the most stupendous works of engineering skill and enterprise of ancient or modern times. We have been in the habit of crediting the new world with some of the most daring and enterprising improvements, but we can boast of nothing that surpasses this. Says the exchange referred to: "Somewhere about 3,000 workmen, 600 or 700 wagons, 17 or 18 locomotive engines, 3 steam 'navvies,' and a great quantity of minor machinery of various kinds have been engaged since 1875 at the southeast end of London in a work, compared with which the building of the pyramids—with modern appliances—would have been no very signal feat. Hitherto the one entrance to the Victoria docks from the Thames had been at Blackwall point, but now there is a dock capable of receiving all vessels, no matter what they might be. Three and a half miles of walls have been built, enclosing 90 acres of water. These 'walls' are 40 ft. high, 5 ft. thick at the top and 18 ft. thick at the bottom, the whole of this enormous mass being composed of solid concrete, for which 80,000 tons of Portland cement have been used. Some 4,000,000 cubic ft. of earth have been dug out. It may assist the imagination somewhat to state that if it were filled into ordinary carts, the vehicles would form an unbroken line 7,000 miles long. The excavations have gone through submerged forests; and, among other curiosities dug out, have been a reindeer's horn, a Roman vase, and what is supposed to be an ancient British canoe, carved out of solid oak. The latter is now in the British museum. The new entrance below Woolwich will save about three and one-half miles of river navigation, which, in the case of vessels of heavy draft, is of course a matter of very great importance."

Mr. Law's Report on the Tay Bridge.

The Commissioners to investigate the cause of the Tay bridge disaster, Messrs. Rothery, Barlow and Yolland, employed Mr. Henry Law, M. I. C. E., to examine the bridge after the fall of a portion of it to make a report thereon, which could be used as evidence on the trial. As a result he submits a long report, in which his conclusions summed up would make the statement appear as follows: The base of the pier was too narrow, occasioning a very great strain upon the struts and ties, that the angle at which the latter were disposed, and the mode of connecting them to the columns were such as to render them of little or no use, and that the other imperfections which have been pointed out, lessened the power of the columns to resist a crushing strain; and further that the yielding of the struts and ties was the immediate cause of the disaster. Some of the other imperfections alluded to were, first, the defective mode of connecting the columns at the flange joints, the bolts being one-eighth inch less in diameter than the hole, and the flanges being separated in some cases as much as three-fourths of an inch. The concrete was also found to be bad, on account of its inequality. The mode of attaching the ties to the columns by means of lugs was evidently insufficient, as in almost every instance the lugs have been torn away.

THE ENGLISH CHANNEL TUNNEL.—It is asserted that within 18 months two and a half miles of the proposed channel tunnel between England and France will have been excavated, and that the work will be completed in four years, probably by boring from each end. There are evidently, however, contingencies, such as a break in the rock, which may destroy the whole enterprise. Meantime another bold scheme for crossing the channel contemplates a line of steel tubes 16 ft. in diameter, halled so as to make it weigh one and a quarter tons to the foot less than the water displaced, and held at a depth of 35 ft. below the surface (so as not to impede navigation) by being anchored by chains to caissons sunk to the bottom. Through this floating tunnel of 20 miles or so it is proposed that railway trains shall pass. The scheme appeals rather too strongly to credulity.

IMMENSE AGRICULTURAL MACHINE PROPOSED. Mr. Theodore T. Woodruff, inventor of the parlor sleeping car, described, at a recent meeting of the Franklin Institute, his steam motor for cultivation of the soil—an immense machine, estimated to weigh, with water and fuel, about 25 tons, and, as arranged for plowing, estimated to turn 132 ft. per minute. In the drawing the machine was represented with 15 plows, each designed to turn 14 inches wide, so that the machine would prepare ground for a width of 17 ft. 6 inches, at the rate mentioned above. The motor is guided as well as driven by steam, and the plows are adjustable (within limits) to any desired depth, over three acres being calculated as the work possible for the machine. The motor may also be adapted for ditching, grinding, thrashing, sawing, etc.

USEFUL INFORMATION.

THE LARGEST SEWING MACHINE IN THE WORLD.—Mention has already been made, says *Design and Work*, of the modifications of the Singer sewing machine to adapt them to certain kinds of work. The latest of these we must allude to more prominently, and introduce the reader to the largest sewing machine in the world. This gigantic stitcher has just been completed, and may thus be described:—The machine weighs over four tons, and is in some respects of new design, uniting much simplicity of construction with great strength of parts. It is adapted for general manufacturing purposes of the heavier sort, although specially made for stitching cotton belting, an article which is just now taking the market as a cheap and serviceable institution for gasing and the ordinary leather belting. The material used is of great strength and toughness, and is sewed together in plies or layers up to an inch in thickness. The belting in being sewed together is passed through heavy feed rollers some nine inches in diameter and over eight ft. in length, getting stretched and pressed in the process. There are two needles at work, with two shuttles, and the shuttles can be removed from the bottom without disturbing the overlying plies of belting. The rollers between which the work passes are actuated by reversible worm and cam motions, and the machine has, in addition to these roller-feeds, what is known as a top-feed motion, suitable for a lighter class of work. The stitch, as in the ordinary sewing machines, can be easily adjusted from one-eighth inch upward, and the pressure of the rollers on the work passing through the machine can be regulated at the will of the operator. The machine, which is driven by steam, has been made for a manufacturing firm in Liverpool.

THE USE OF COPPER BY THE ANCIENTS.—Copper is widely spread over the face of the earth, and man, in all ages, has adapted it to his wants. It was one of the greatest articles of commerce with the Phenicians, who derived a large supply from the mines of Nubia, that at one time supplied the whole of the known world, and combined with it the tin obtained from the islands of Great Britain. It was used by some of the northern nations of Europe in the fabrication of weapons, at a period and under circumstances when steel appeared to be more precious than gold. This has been illustrated in Denmark, by the opening of many Scandinavian tumuli of very remote ages, and from which have been collected specimens of knives, daggers, swords and implements of industry, which are preserved in the museum at Copenhagen. There are tools of various kinds, formed of flint, or other hard substance, in shape resembling our wedges, axes, chisels, hammers and knives, the blades of which are of gold, while an edge of iron is attached for the purpose of cutting. Some of these tools are formed principally of copper, with edges of iron, and in many of these implements the profuse application of copper and gold, when contrasted with the parsimony evident in the expenditure of iron, seems to prove that at that unknown period, and among the unknown people who raised these tumuli, gold as well as copper were much more common products than iron.

QUICK-SPEED CIRCULAR SAWS.—Soft-iron discs running at a circumferential speed of 12,000 ft. per minute will cut hard steel, but 5,000 ft. per minute will not cut iron. This fact is taken advantage of in rolling-mills to cut large bars and beams to exact lengths. At the L. & N. Western railway works at Crewe, the circular saws for cutting hot steel have a velocity of 13,000 ft. per minute at the periphery, equal to a speed of about 150 miles per hour. The saws are 7 ft. diameter, and 5-16 inch thick, driven through gearing in one case by a pair of locomotive cylinders 17 inches diameter and 2 ft. stroke; in another instance the saw is driven direct by a three-cylinder engine, 14 inches diameter and 8-inch stroke. At another works a saw of 4 ft. 6 inches diameter is run at 1,200 revolutions per minute, equal to 17,000 ft. per minute. A jet of water plays on circumference of saws to keep them cool.

BURNT ALUM.—Ordinary alum is a double sulphate of potash and alumina, containing, when crystallized, 24 molecules of water. When heated, it melts in its water of crystallization, and on continued heating this is expelled, leaving a dry powder, known in pharmacy as *Alumen usta*, or burnt alum. That sold at the drug store is often imperfectly dried, and should be placed for an hour or more in a hot hake oven before use. According to C. Bernbeck, the best test for a good article, is nearly tasteless when put on the tongue, and takes 12 to 24 hours to dissolve in water. Much of the alum now in commerce contains no potash, the alkali being ammonia. Of course ammonia alum cannot be converted into burnt alum, as the ammonia is expelled at the same time, leaving only sulphate of alumina behind.

BONE GLASS.—After extracting phosphorus from bones, a glass can be formed from the residue which consists of lime and phosphoric acid, the ordinary kinds of glass being composed of sand and potash, soda, lime and alumina. Bone glass can be worked as readily as any other glass; it has the valuable property of not being attacked by fluorine acid.

PERFORATING GLASS BY ELECTRICITY.—A simple method of perforating glass with the electric spark is described by M. Pages in a recent number of *La Nature*. The apparatus required consists (1) of a rectangular plate of ebonite, its size, for a coil giving 12 ctm. sparks, about 18 ctm. by 12; (2) of a brass wire passing under the plate, and having its pointed end bent up and penetrating through the plate, not farther. This wire is connected with one of the poles of the coil. A few drops of olive oil are placed on the ebonite plate about this point, and the piece of glass to be superposed, care being taken not to imprison any bubble of air. The olive oil perfectly accomplishes the object of insulating the wire. One has then only to bring down a wire from the outer pole of the coil, on the piece of glass, above the point of the lower wire, and pass the spark. By displacing the glass laterally for successive sparks, it is easy to make a close series of holes in a few seconds.

BEST SUGAR PRODUCT.—The continent of Europe now produces from beets more than one-fourth of all the sugar of all kinds made in all parts of the world. France makes 451,000 tons; Germany, 290,000; Austria, 205,000; Russia, 150,000; Belgium, 80,000; Holland and Sweden, 35,000—in all, 1,211,000 tons. France has about 500 sugar factories, and about as many distilleries for beet spirits and for beet sugar molasses. In this country capitalists are awakening to the importance of this branch of manufacture, and already immense establishments have been organized in some of the Eastern States. The prairies of the West afford the finest field for the cheap production of the beet.

GRAPEVINE LEAVES AS HOPS.—Did any reader ever try using grapevine leaves instead of hops in bread-making? Simply use grape leaves as though they were hops, only, perhaps, requiring a little larger quantity. After having made yeast, just before setting it to rise, stir into it from one-half to one teaspoonful (according to quantity of yeast) of light hop yeast, or that made by soaking yeast-cake in a little warm water, stirring in the flour and allowing it to rise. After the yeast has become light, use as you would hop yeast. While the leaves on the vines are still fresh and green, gather the tenderest and best, dry and save for winter use.—*Inter-Ocean*.

The largest sheet of plate glass in the world has recently been cut at the St. Gobain works in France. It measures 21.15 ft. by 13.43. It is 7-16 of an inch thick. It is white glass and weighs 1,573 lbs. The same works have turned out a silvered mirror 17.90 by 9.94 ft., weighing 770 lbs. The Jeumont works have produced a plate of white glass 17.81 by 11.51 ft., which weighs 1,100 pounds.

PICKLING CUCUMBERS.—To make them keep firm and brittle through the year, steep in strong brine for a week; then pour it off, heat it to boiling, and pour it over the cucumbers. In 24 hours drain on a cloth, pack in wide-mouth bottles, fill these with strong hot pickling vinegar, and seal at once. Various spices are added in the bottles.

CHINA MOSS.—The curious substance known as China moss has a peculiar constituent called gelose, which has the property of absorbing and solidifying into a colorless and diaphanous jelly, 500 times its weight of water, and is capable of forming 10 times as much jelly by weight as the best animal gelatine.

SAND is worked with cement to keep the latter from cracking, to harden it and to lessen the cost of the mass.

GOOD HEALTH.

Eye-Sight.

Milton's blindness was the result of over-work and dyspepsia.

One of the most eminent American divines having, for some time, been compelled to forego the pleasure of reading, has spent thousands of dollars in value, and lost years of time, in consequence of getting up several hours before day and studying by artificial light. His eyes never got well.

Multitudes of men or women have made their eyes weak for life by too free use of the eye-sight, reading small print and doing fine sewing. In view of these things, it is well to observe the following rules in the use of the eyes:

Avoid all sudden changes between light and darkness.

Never begin to read, or write, or sew for several minutes after coming from darkness to a bright light.

Never read by twilight, or moonlight, or of a very cloudy day.

Never read or sew directly in front of the light, or window, or door.

It is best to have the light fall from above, obliquely over the left shoulder.

Never sleep so that, on the first waking, the eyes shall open on the light of a window.

Too much light creates a glare, and pains and confuses the sight. The moment you are conscious of an effort to distinguish, that moment cease, and take a walk or ride.

As the sky is blue and the earth green, it would seem that the ceiling should be a bluish tinge, and the carpet green, and the walls of some mellow tint.

The moment you are prompted to rub the eyes, that moment cease using them.

If the eyelids are glued together on waking up, do not forcibly open them, but apply the saliva with the fingers—it is the speediest diluent in the world—then wash your face and eyes in warm water.—*Exchange*.

This has been going around for about 10 years, and its ownership, we guess, is lost; but it is good enough to go on indefinitely.

PEDESTRIAN EXERCISE.—In pedestrian exercise for pleasure, sport, or health, much power may be saved by skillfully balancing the spine on the pelvis, and so adjusting and harmonizing the movements of the upper and lower extremities ("getting the swing" as it is called), that the force of gravity does a great part of the work. This is the great secret of the professional pedestrian, whose object is to economize strength, not to expend it. This art is easily acquired, and even a delicate lady, with a week's practice, can cover a distance which at first would seem impossible. But one of the first essentials of true exercise is resistance. There must be some obstacle to overcome, some weight to be lifted, if we would break down muscular tissue and build up with new material. This resistance, a moderate walk will never give. One must needs walk ten or twelve miles a day in order to get exercise enough to keep the body in a healthy condition. To accomplish this task requires from two to three hours. Aside from the benefit to be derived from the inhalation of fresh air, the same amount of exercise may be taken in twenty or thirty minutes by lowering and raising the body, alternately, flexing and extending the legs, by taking a short run, or by making a few excursions to the top of a seven-story building.

RESPIRATION AFFECTED BY FOOD.—A very careful examination by Dr. Speck, of the changes produced in the respiratory process by the use of fatty food, of coffee, quinine, alcohol and water, and by the inspiration of air respectively rich in carbonic acid, poor in oxygen and rich in oxygen, has led him to the following conclusions: With an increased proportion of hydrogen in diet, the amount of air inspired and expired decreases, and nutriment, such as sugar, which contain little hydrogen in comparison with their oxygen, involves more exertion of the respiratory organs than such as are rich in hydrogen like the fats; the more carbon predominates in the food, in proportion to hydrogen, the more air is exhaled in proportion to that inhaled, the more carbon increases in the diet in proportion to hydrogen, the more carbonic acid is evolved and the more oxygen is taken up—while the richer the diet in hydrogen the less oxygen is required. An atmosphere containing 5% or 6% of carbonic acid could be breathed for some minutes without oppression; at 11.51% great exertion would be needed to breathe for one minute; at 7.2 all carbonic acid produced in the body is retained in the blood.

HALLUCINATION OF THE SENSES.—Prof. Maudsley remarks, in a recent lecture, that one striking feature observed by medical men who have had cases of hallucination under their charge is that the patients cannot be convinced that the objects they see, the sounds they hear, and the smells they perceive, have no real existence, and that the sensations they receive are the result of their excited nerves. It frequently happens, too, that a person who suffers from hallucination in respect of one sense has the others unaffected, and is, on all other matters, perfectly normal. Hallucination may arise either from an idea on which the mind has dwelt, appearing as something exterior, or from excitement of the sensory ganglia. It is said that Newton, Hunter, and some others of equal professional eminence, could, at will, picture forms to themselves till they appeared to be realities.

TABLET SALT AN APERIENT.—Physicians have for a long time known that common table salt is an efficient aperient in ordinary cases of constipation. In a lecture on a case of nervous affection, Dr. Weir Mitchell, of Philadelphia, said that he had recommended the patient to take each morning on rising a tumblerful of water—cold, to prevent nausea—in which was dissolved a teaspoonful of table salt. "This simple aperient," the doctor adds, "I frequently employ in cases of constipation, and generally find it efficient. There is great advantage in starting the bowels and in keeping them in a soluble condition, particularly in cases of nervous disorder in women, as it sometimes clears up obscure points in the case, and at all events eliminates one source of error."

DISEASES OF COAL-MINERS.—The Belgian Academy of Medicine has received a report on the researches made by Dr. Fabre regarding the disease to which coal-miners are especially liable. He finds that as coal absorbs rapidly up to 100 times its own volume of oxygen, the air which the miners have to breathe is deprived of oxygen to a hurtful degree. The atmosphere of a mine is also further vitiated by the gaseous carbon compounds given off by the slow combustion of the coal. He concludes that a supply of air is more essential than an empty of light, and that even the best ventilated mines need to be better ventilated.

The Mineral Resources of Washington Territory.

No. 1.

A SERIES OF ARTICLES PREPARED FOR THE MINING AND SCIENTIFIC PRESS BY OUR RESIDENT CORRESPONDENT, ELDRIDGE MORSE.

THE SKAGIT GOLD MINES.

The world knows all about the golden wealth found in the streams and mountains of California. Thousands have penetrated to the most inaccessible parts of British Columbia, and have visited the shores and mountains of far northern Alaska in search of the precious metals; but this is the first season that the general attention of the Pacific coast has been directed to Puget sound as a center of mining enterprise, or to the Cascade mountains in Washington Territory as depositories of mineral wealth in gold and silver, in quantities sufficient to compare with its neighbors to the northward or to the southward. None could give any good reason why these precious metals should not be found in these mountains in quantities as great as they have been produced to the northward and to the southward, in such prolongation of the same system of mountains, except that all previous efforts had to a certain extent been unsuccessful. No large quartz mines had been opened up, and no extensive placers, until recently, been struck.

These things have most undoubtedly produced a tendency to sneer at the possibility of ever finding mines as rich in Washington Territory as have been found in California, Nevada or British Columbia. Still, within the past few years, both placer and quartz mines have been found that promise to equal those in British Columbia and Alaska, and possibly to compare favorably with those of California and Nevada. A wide gold-bearing belt undoubtedly exists, crossing the Territory from north to south, the limits of which may be described in subsequent articles. In this number an attempt will be made to give a concise outline of what is already known in reference to

The Mines on the Skagit River.

Like every other river flowing into Puget sound, fine float gold can be found the whole length of the Skagit. In some places the deposits are rich enough to afford small wages to those who are willing to work them.

In 1860 an Indian woman picked up a nugget of gold near the mouth of the Sauk, some 60 miles up the Skagit, which she sold to the Puget mill company at Port Gamble for \$27.

Ever since that time every little while attention would be called to coarse gold brought from the Skagit by the Indians; but prior to 1878 no specimen of coarse gold had been found by white men on that river or its tributaries; at least no report of such finding has so far been made public. Had anyone found coarse gold, the public by this time would have heard of it.

Prospecting that led to the present excitement began in 1877. From five to seven men were at work during the summer and fall of 1877 prospecting the Skagit and its tributaries, finding in many places good prospects of fine gold on the surface, but failing to discover coarse gold. Prospecting was resumed in February, 1878, when a party went nearly up to what is now called Ruby creek. All but two of the party stopped at the Tunnel canyon, some six miles below the creek. The two who went on—John Rowley and John Sutter—struck coarse gold about two miles up Ruby creek. They found in one pan one dollar and a half. They found so many small rubies in the black sand that they named the stream Ruby creek at that time. Then, prospecting up the Ruby, they struck coarse gold in several places. This stream is about eight miles long, and is formed by the union of two streams, since named Granite and Canyon creeks. These men prospected up both of these, but found prospects only on Canyon. They then prospected on Skagit, above the mouth of the Ruby, and found plenty of fine gold, but no coarse. On returning to the Tunnel canyon, another party was met coming up. In June, 1878, of this second party, Rowley, Conn, Duncan and Presentine went up the Skagit, ten miles above the mouth of the Ruby, and failed in trying to cross the mountain into Ruby and the head of Canyon creeks; then they came down to the mouth of Ruby and went up that stream. They panned out some \$15 worth of coarse gold near its mouth. They also found coarse gold up Ruby and Canyon creeks, but were compelled to return for provisions. A freshet came on while their supplies were near the head of canoe navigation, some 16 or 18 miles below Ruby. The freshet had carried off their canoe, leaving them on one side and their supplies on the other, and the river was too high to attempt crossing, and they had to travel nearly three days without food. In September, 1878, Rowley and Presentine were on Ruby again. They found bare bedrock on Canyon creek, and in one day took out \$20.

Having no provisions, tools, etc., they struck out for supplies, and met Sanger, Woods, and Armstrong at the Tunnel House, and again went up Canyon creek, where, in two hours,

the five took out some \$45. They obtained some \$68 in all that day. In November, 1878, Messrs. Rowley, Armstrong, Woods, Pierce, and Cassy went in and wintered on Ruby. Cold weather and deep snow prevented them from accomplishing anything to speak of. But in February, 1879, they organized Ruby mining district. Representation day was fixed at July 1, 1879, on which day there were 29 men there; but high water, lack of tools, and other difficulties prevented them from accomplishing anything for a couple of months, and so discouraged the men that half of them were about leaving in disgust. On the last Saturday in August, 1879, several of the party were encamped about two miles below the head of Ruby, having left Canyon creek, on their way out. One of them, Berney McCort, took his pan and crossed the creek. In 20 minutes he took out some two dollars. Five others soon joined him, and that evening they took out \$22. These six men stopped there and formed the Nip and Tuck company, which took out nearly \$800, in six weeks. Then one or two of the company stopped after the rest left for this season, and took out enough more, so it is estimated, to make \$1,000 secured by that company of six men last fall.

Rowley and Presentine, with four others, tried for two months, unsuccessfully, to work the Discovery claim, on Canyon creek. They left about the 1st of September, 1879. When going out they met Sanger and Duncan, and gave them authority to clean up their cut, etc. Armstrong joined them. The three cleaned up \$283 from the abandoned cut and bedrock in a few weeks. In not over six weeks, during last September and October, some \$3,000 was taken out by these three miners. Perhaps as much as \$4,000 in all was taken out last fall. About 60 men in all visited the mines that season; but not over 25 did any work to speak of. The gold taken out last fall was what created the great excitement last winter, and caused the rush to that locality over the snow, until, at the present time, some 1,200 men have visited the mines, over one-half of which number have taken up claims. What the present outlook is will be best understood by

A Brief Description of the Skagit River

And that section of country. This river is about 175 miles long. It rises in British Columbia, not far from the Frazer. One of its tributaries rises within 14 miles of Fort Hope. About 10 miles north of the line the west fork joins it; then for 30 miles the stream flows nearly south to the mouth of Ruby, and except for the jams, the river is navigable for canoe all this distance. For this distance the river bottoms are three miles wide, with timber, climate, etc., like those found on the eastern slope of the Cascade mountains. This is a very peculiar valley, with high mountains each side of it. Mount Baker lies just west of it, 10,000 ft. high; while the main range of the Cascades, from 6,000 to 7,000 ft. high, is just east of it. About half way between the mouth of Ruby and the British line is Lightning creek, which, like Ruby, flows into the Skagit from the east. The tributaries on the west are Eagle creek and Beaver creek. The development of the mines will cause this mountain valley to be settled by hundreds of families, who will grow produce for the mines.

Below the mouth of Ruby the Skagit is a terrible river for some 16 or 18 miles until Goodell's, the head of canoe navigation, is reached. It is but little more than a series of wild-cascades, flowing through a succession of very deep and narrow canyons. One of these, some six miles below Ruby, is called Tunnel canyon.

A Remarkable Canyon.

Here also comes in from the east Thunder creek, through a canyon two miles long and 250 ft. deep, and so narrow on top that a man can almost step across it. The creek is nearly 40 ft. wide. In flowing through this canyon it makes a noise like rolling thunder. Its mouth is near the upper end of Tunnel canyon. Here the river was supposed to flow under ground for nearly a mile, and the first prospectors there described it as an "underground tunnel." From above, below and each side it has that appearance. It is only by going to the edge and looking down two or three hundred ft. into the narrow and deep chasm which yawns beneath you that the mistake is discovered. Ruby also flows into the Skagit through a very narrow canyon. For some six or seven miles below Goodell's, although navigable for canoes, the river is very swift and wild, large boulders in the center of the stream and some bad riffles; then comes the portage, where the boulders are so thick and the fall so great that none but the most skillful can or dare shoot through. In times of high water the waves roll over the boulders from six to 10 ft. high. In very low water the waves may not roll over two or three ft. high, but the boulders are so much thicker on the surface of the water that the dangers are nearly as great. The worst part of this portage is only some 300 yards long, but there are very bad riffles just below the main portage. It was in these riffles six men were drowned on the second of May, 1880. Canoes and hats usually are taken through this place with a line, while the freight is all packed around it. In going down only a small portion try to shoot through. Then, no matter what is the skill, a mistroke will consign the whole outfit to a watery grave. At the time of the accident above referred to, the passengers walked around the portage, while the two in charge, Dave Ball and an Indian, shot through all right; then above the lower riffles they took in the 10 passengers; the canoe was fit to carry

six; she swamped; Ball was drowned and five passengers with him; the others were saved by a passing boat. Had this canoe a smaller load, or had the passengers walked 300 yards further, all would probably have got down safely.

Below the portage the country grows gradually smoother, the river easier to navigate, and it is but a short distance to where the valleys are wide enough to cultivate. The ranch of the Cascades, of which Mount Baker is the highest peak, may be said to cross the Skagit river at the portage, which is a very narrow canyon, cut across very high mountain through which the river flows.

Portage City.

Three miles below the portage is Portage City, the supposed head of steamboat navigation. Most of the year steamboats of sufficient power can reach here, although none have gone farther than the mouth of the Sauk, 2 miles below. From Portage City there are no real obstacles to canoe navigation but what are surmounted by hard work; the riffles are some of them, swift, but not dangerous to skilful canoe men. The Sauk is the present best agricultural settlements. Here is a beautiful tract of very fertile land, where there is enough vacant to make homes for hundreds of families. Doubtless it will all be occupied before long.

Eight miles below the Sauk, the Bear river flows into it from the north. It drains the southern slopes of Mount Baker. Fourteen miles below Baker are

The Skagit Coal Mines.

The mine is called the Cumbsland, and account of the forging qualities of this coal, at its resemblance to the celebrated Cumbsland coal. Some seven or eight miles above the mines, the fertile low lands of the Skagit are 10 miles wide, with only a few settlers on the river bank. It is about 16 miles from the coal mine to Sterling, which is quite a logging center and 10 miles from there to Mount Vernon, which is 12 miles from the sound. Mount Vernon is one of the best known points on the river and the usual stopping place for sound steamer, and where most of the minor start in canoes to go up the river. It is expected that after another steam or ice travel will be sufficient to induce steamers to go regularly as far up as the Sauk, and perhaps to Portage City. The country around the mouth of Skagit is considered the most productive in western Washington.

The Snowfall.

Last winter snow fell the heaviest in the mountains and on the sound ever known since the Hudson Bay Company first were here. The forepart of January, in a single week now fell over four ft. deep at Seattle and other points on the sound. In the open places, near the water, it melted nearly as fast as it came; but in the timber back from the water, and in the mountains, it fell much heavier and did not melt. The 1st of March, 1880, the snow probably averaged 10 ft. deep in the mountains. This deep snow commenced falling about the same time as the rush to Ruby creek began last winter. It caught a large number on their way in, just above Goodells. The soft snow was so deep and snow slides so frequent that the first party who broke the trail were 12 days going some 16 miles. After the trail was well broken, a man would carry 80 lbs. and go in in one or one-half days. The troubles of the first lot discouraged some others, so they concluded to try to come in via Fort Hope. There was a wagon road 14 miles from Fort Hope to where it struck the Skagit, thence seven miles farther down it, and an Indian trail to where the two forks joined (at a place named the Steamboat Landing) at the head of the upper valley. Some 10 miles from the boundary and 30 miles from Ruby. Here they were to come down a foot along the bottoms. There were no stables to a summer pack trail on this route, the terrible snowstorms of the past winter so difficult to overcome that the men who came in that way were from 17 to 42 days on the trip. The average was about 30 days. All went out via Goodells and down to Skagit. Some 50 or 60 came in via Fort Hope.

The water in the Skagit river is highest in early summer and lowest in winter. On the tributary streams in the mountains, melting of the snow makes high water often times until late in summer, and low water during the fall and winter.

Ruby Creek

Is about 40 ft. wide, swift and with many boulders in the channel; three miles it runs through a canyon so narrow it can be worked only by fluming. At extreme low water it contains about 7,000 miner's inches of water, flowing under one-ft. head. A flume made so the claim there could be worked eight months out of the year, would have to be large enough to carry some four times that amount of water. Winter is the best time to work most of the claims, on Ruby creek, if they are only first opened in the fall.

Canyon and Granite Creeks

Are each nearly one-half the size of Ruby. The past season gold was first discovered in Granite creek, of quality and in quantities sufficient to induce men to take it up. There is very little float gold on Granite. Canyon creeks some 15 miles long. Its chief tributaries are Mill, State and Gatten's creeks. All Ruby is supposed to be taken, 10 miles Canyon, about 8 of Granite, State and Mill creeks, while a number on Gatten's, Cedar and other small creeks, are also claimed. Near the mouth of Ruby, in several places, gold simi to that in the bed of the creeks has been found in the

mountains several hundred feet above the bed of the creek. Something over \$100 has been washed with snow water there this spring. About \$200 has been also taken out near the mouth of the creek this spring with pan and rocks.

There is a separate mining district for Ruby, Canyon and Granite creeks. Besides these three, another district called Enreka district exists, embracing Lightning creek and its tributaries, where excellent prospects are supposed to have been found on one of its branches, formerly called Three Fools' creek, but now named Eureka creek. Some 40 claims are taken in that district.

About 70 claims are taken on Thunder creek, where is also another district.

This is a very wild and exceedingly rough country, in the most inaccessible part of the Cascade mountains. The gold is similar to Caribou gold in quantity, quality and location; it is quite coarse, but thus far no nuggets above eight dollars in value have been found. No gold to speak of, besides float gold, has been found except on or near bedrock. This has been reached in but few places, and wherever reached the pay has been well distributed and abundant. In Feb., 1878, no snow was on Ruby creek. In the winter following, snow was not at any one time over three or four ft. deep. Last winter set at fault all previous calculations. Men could have worked most all of Ruby, had they had grub and tools in, and claims opened out last fall, all of last winter, despite this high snow; but in the smaller creeks, where the canyons are narrower, the avalanches have filled the canyons from bank to bank with snow from 20 to 150, if not to 200 ft. deep. In many places it has brought down masses of timber, rocks and earth that will be very difficult of removal. The writer traveled for several days over streams that were hidden from sight by snow drifted in, or carried by avalanches, so that for miles at a time the stream would be invisible. There are some of these small streams that poor men could work profitably, if it were not for these avalanches. As it is, about one dozen companies will be almost certain to make money this year; others will make expenses, and others, a greater number, will make little or nothing. With but few exceptions, so far as discover these are not poor men's mines. There is doubtless, plenty of gold on the bedrock will well pay to get it out; but it requires talent and experience to handle it. The chief evil of these mines to poor men will be that of claims to strong companies, and who may make working for wages for the companies two or three years from now, as mines are well opened. It will probably term of years to wash them out. They will do well if they finish prospecting in good pack trails, and a few take that will fairly represent the mines. But little gold can be found before August. A trail for pack put in from Fort Hope, and etc., will probably put in an ent foot trail from Good cross from Granite creek stream flows into the Portage City. It goes over the trail to it from the east, and is a bigable

SAN FRANCISCO:

Saturday Morning, Aug. 7, 1880.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—How Miners Work in America; Rich Mines in Idaho; The Zimmerman Fruit Drier, 81. The Week; The Industrial Exhibition; Academy of Sciences, 88. The Mining School at Berkeley; The Winged Phylloxera; The Aztec Lizard, 89. Notices of Recent Patents, 92.

ILLUSTRATIONS.—The Zimmerman Fruit and Vegetable Driers, 81. Fertile and Infertile Forms of Winged Phylloxera; The Aztec Lizard from Arizona, 89.

CORRESPONDENCE.—Silver in the Coast Range; North Bonanza, Flowsy District; Putting on Battery Screens, 82. Letters from the Comstock, 89.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 84.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho and Montana, 84-86.

MISCELLANEOUS.—The Jamin Electric Light; A Curious Railroad; Mining in Utah; The Peril of a Miner; Experiments in Making Diamonds, 82. Mineral Resources of Washington Territory—No. 1; An Overworked People, 86. The Mechanics' Institute Fair, 90.

MECHANICAL PROGRESS.—Founding in Steam Engines; Speed of Pulleys and Belts; Glass Millstones; Facing Sheet Iron with Nickel; The Relative Cost of Motive Power, 83.

SCIENTIFIC PROGRESS.—Pasteur's Important Discovery—Cause of Cholera in Fowls and its Prevention; The Nebula in the Pleiades; Decomposition of Powder in Cartridges; Bees and Flowers; Testing Alcoholic Liquors, 83.

THE ENGINEER.—Another Great Engineering Work Completed; Mr. Law's Report on the Tay Bridge; The English Channel Tunnel; Immense Agricultural Machine Proposed, 87.

USEFUL INFORMATION.—The Largest Sewing Machine in the World; The Use of Copper by the Ancients; Quick-speed Circular Saws; Burnt Alum; Perforating Glass by Electricity, 87.

GOOD HEALTH.—Eye-sight; Pedestrian Exercise; Respiration Affected by Food, 87.

NEWS IN BRIEF on page 92 and other pages.

Business Announcements.

Dividend Notice—Standard Con. M. Co.

The Week.

Notwithstanding the cool and bracing summer weather, and the general good health of the city, several cases of smallpox have been detected in the Chinese quarter, which is, unfortunately, in the central part of early San Francisco. As soon as the presence of the disease was detected—for the Chinese neglect or refuse to voluntarily give the information of its existence among them—the usual precaution of vaccination was resorted to by many residents in the vicinity of the infected quarter. Since its discovery, the Board of Health has been active, and the fumigation and cleansing of the Chinese quarter has been carried on systematically. There is no apprehension that the disease will become epidemic.

The Territory of Alaska presents a condition that is neither creditable to the government nor assuring to our enterprising citizens who have engaged in venture there. The latest attempt to arouse the attention of the authorities comes from Mr. Walter Blaine, a son of the Senator, who again points out the oft-repeated fact that the Territory is really without any government, and urges that a simple and cheap one ought to be provided. At least the common law of the country ought to be extended over the Territory, and proper judicial officers appointed to administer it. Anything would be preferable to a condition of active or latent anarchy.

Next week the Fifteenth Industrial Exhibition of the Mechanics' Institute will commence at the Pavilion. It gives promises in all its excellent features of being the most attractive exhibition of the material wealth of the State which has occurred in this city for years. The premium list is unusually liberal, and ought to excite, as it doubtless will, a spirited and interesting rivalry.

Since our last issue there has been an important development of good ore in the workings connecting the Sierra Nevada and Union Con., and the news has done much to revive the share market. Equally good news has been received from Bodie, where ore has been discovered at the greatest depth yet reached in any mine in the district. These assuring reports from two important districts have had a marked effect in restoring confidence.

The Industrial Exhibition.

The Fifteenth Industrial Exhibition of the Mechanics' Institute will undoubtedly be the notable incident in the affairs of our city and State during the year. It will disclose the condition of our material wealth, of our industrial progress, of our advance in art and taste, and will, in a large degree, mark our social and political standing. The soil of California is as varied and as fertile as her area is extensive, and the use which her people have made of her boundless natural resources will be spread open at the coming fair like the leaves of a book. This industrial exhibition will be a fair and comprehensive exponent of the manner in which our fields and vineyards and gardens are cultivated; it will reveal the methods of our workshop, and show the scope and spirit of our invention no less than the skill and cunning of our manipulation; and it will disclose the measure and the quality of our taste in art and all aesthetic culture. In fine, the exhibition of our varied handicraft will be a revelation of the very body and spirit of the State, and it will enable the observant critic to mete the full measure of our deserts as a civilized community.

So far as the action of the managers of the Institute is concerned nothing appears to be left undone to make this exhibition the marked success of the series. They have invited co-operation not only from the citizens of California but from the entire coast; they have offered a munificent premium list, which is unrivaled in scope and quality; and it would appear that the Institute must achieve the brilliant success which its managers have taken such pains to command.

A conspicuous feature of the exhibition will be the fine horticultural display. It will be the fullest, the most complete collection of herbs and plants which has been exhibited in this State for many years, and will convey some adequate idea of the floral grandeur of our California. In order that this department shall be properly provided and cared for, the managers of the exhibition have arranged with the State Horticultural Society to take special charge of it, and to render it a fair exposition of the horticultural capabilities of our State. Judge will be appointed with special reference to their fitness for examining the articles submitted to them; and the premiums will be awarded upon the recommendation of such committees as the society may appoint. This arrangement ought to insure full satisfaction to the exhibitors.

The State Vinicultural Society will also have a special department adjoining that of the Horticultural Society. It is left to the exhibitors to determine the rules of this exhibition. An interesting feature of this department will be the trial room, where on certain days the wines exhibited may be tried by experts, and as full reports of each exhibit will be made and printed in the proceedings of the Institute, these trials will be of substantial advantage to every exhibitor of the product of the vineyard.

The display of manufactures and inventions will be a prominent feature, and the interest in the skill of our artisans and inventors will be lively and general. It is promised that the exhibition of mining machinery shall be the most complete in variety and extent which has been seen in this city for a number of years; and as mining and milling apparatus is a marked specialty of California, this department will command special and critical attention. Mining machinery is a unique feature of California skill. Nowhere else is the field so large or the expert workman so numerous. For upwards of a quarter of a century, men, already skilled in the fabrication of general machinery, have had a special training in the manufacture of machinery and apparatus for the most varied and stupendous mining operations in the world. As a consequence our machine shops are full of experts, and are under the control of the best equipped engineers. In the production of mining machinery California is easily first and unrivaled.

In addition to those large and distinctive features, the exhibition will comprise the endless details of a variety of ordinary and curious industries, an examination of which will not fail to give pleasure and instruction. The man of affairs, whether he be manufacturer or artist, farmer or inventor, will not miss the material for thought and profit in the collected products of the State; while our young men and women, our boys and girls, will find no better school in which to learn to observe the methods of civilized life; to perceive, and in some measure understand, the nature of the industrial arts by which communities promote their comfort and happiness. The lessons learned by them may prove strong incentives to exertion and purpose, and finally lead to useful and honorable careers.

A RUMORED ENTERPRISE.—It is rumored at Grantville, Nye county, Nev., says the *Austin Reveille*, that a company of capitalists has arranged for sinking a shaft 1,000 ft. in depth on a series of locations recently made, adjoining the Alameda, in the mountain west of the town of Grantville. The enterprise is in the hands of men who have had large experience on the Comstock, and if carried out as reported means mining in a scientific manner.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held Monday, August 2nd, with Dr. Hermann Behr in the chair. The donations to the museum comprised, among many valuable gifts, a large and beautifully-mounted collection of butterflies, from Mrs. J. H. Sargent; a *Raia stellulata*, from Prof. David S. Jordan; a *Telephonium*, or big bug of Mexico, from Vice-President Justin P. Moore, and a large piece of American graphite, or plumbago, weighing several hundred pounds, from the graphite mines at Ticonderoga, N. Y. Several large volumes of astronomical records were received from Cambridge observatory, Harvard college, etc.

Mr. Volmar A. Hoffmeyer was elected a member of the academy.

Dr. Kellogg, the eminent botanist of the coast, read a description of a new and exceedingly beautiful large violet-blue Gentian found by Mr. G. W. Dunn in June last in the mountains east of San Diego, specimens of which are here exhibited, having flowers one and a half inches across; a very dark purple eye or center, with, as it were, a brush-dashed border, fading into blue. The plant grows to a height of about three ft., and may readily prove of marked ornamental interest to florists, and an agreeable addition to gardens.

Besides being valuable medicine. The plant being a new one to science and unnamed in the catalogue of California botany, he took occasion to name it *Gentiana Dunnii*.

Dr. Kellogg then exhibited flowering specimens of a most remarkable harberry tree from Big canyon—the *Barberis Fremontii*—which grows 20 ft. high, and its trunk is three inches in diameter. It was laden with golden glooms, and may be cultivated and made one of the most desirable ornamental shrubs of California. It thrives well on poor, dry, rocky soils, and is celebrated for its medicinal virtues. Its sap furnishes material for making a most powerful yellow dye.

He also presented an unexplained fibrous plant from Lower California, which shoots up a flowering stem 5 or 6 ft. high, and bears an ample mass of small white glooms. He thought it of the Colchicum family of plants, all the varieties of which are valuable remedies, useful in cases of gout and rheumatism. It is good for purposes of thatching, for which it has been used. He proposed to test and study it up, and report its general commercial use at a future meeting. He also exhibited a plant of the *comandra umbellata*, belonging to the family of sandal-wood trees, which has been found in the Sierra Nevada foothills. It bears a delicious nut which squirrels eat with great relish.

Mr. C. D. Gibbs then read a carefully-prepared paper on the

Uses of Graphite, or Plumbago.

Which, he said, was erroneously called black lead. He alluded to the term used in commerce, of "lead-pencils," which he pronounced a total misnomer, because there is never any lead in them. They are all made of graphite, a wholly different substance, which has the same geological parentage or general form of classification as our anthracite coal. It is used to make pencils, crucibles, and portable furnaces; also for lubricating machinery, and giving a stove-polish to iron. He described the manufacture of pencils by the Dixon or American Graphite Company, who now employ 80,000 pencils daily, or over one-quarter of all the pencils used in America, and also the famous Borrowdale mine in Cumberland, England, which was formerly kept closed all but during six weeks of every year, when the quantity taken out was monopolized and sold for several hundred thousand dollars. The most famous mine in now the Aliberti mine, in Siberia, which furnished graphite commanding the highest price in commerce. The paper was a very interesting one, and was offered in illustration of the beautifully foliated specimen presented last evening to the academy.

One of the members reported that several Alameda oystermen, having read the discussion about the King crab, presented at the last meeting, had reported to him that they had, on several occasions, found young ones among Eastern oysters on their arrival, and that no possible doubt could exist that they were introduced on our coast by being brought overland with shipments of young Eastern oysters.

Dr. Henry Gibbon, Sr., made some remarks explanatory of technical Latin names used in botany, after which the academy adjourned.

FLOATING DOWN A FLUME.—Recently on a Sunday evening, says the *Carson Appeal*, a number of ladies and gentlemen, visitors at Glenbrook, went to the summit at the head of the large flume. After witnessing the rapid flow of the water and great quantities of wood in it, one of the party suggested that none present dared take a trip down the flume. An offer of a wager was made and accepted by Wither Harlow and Miss Belle Graham, both of San Francisco. The two foolhardy young folks jumped upon a pile or raft of wood and rapidly floated down the flume for a distance of a mile or more, when a sudden lurch caused them to lose their equilibrium, and they were thrown faces foremost among the wildly tossed wood. A half mile from the place of disaster they were fished out by a couple of flume watchmen, badly bruised and cut up, but otherwise unhurt.

The Mining School at Berkeley.

Whatever is done by the State for the advancement of the mining interests of this coast must be of interest to the readers of this paper. The last Legislature appropriated a few thousand dollars for the equipment of the mining school of the State University at Berkeley. That the investment is a good one for the community will be evident from the following account of the manner in which a portion of the funds is being expended.

The value of a superior mining school to our mining interests can not be overestimated. When the graduates of such an institution become scattered over the mining regions, promoting our mountains and working our mines, cultivated intelligence will take the place of the ignorance and empiricism which too often control at the present time. Such a body of educated engineers, co-operating with the specialists in charge of our mining school, will certainly exercise a powerful influence towards the adoption of the most rational and economical methods in all of our mining operations.

There are three more or less distinct branches to the mining profession, viz: experting, mining engineering, and mill engineering. The expert determines the nature, form, and value of the ore as it lies in the ground, oftentimes before any developments whatever have been made. On this work special knowledge in mineralogy and geology is required. The mining engineer determines the most economical methods of getting the ore to the surface; this demands special training in mathematics, mechanics, and the peculiar methods of tunneling, mining, surveying, etc. The mill engineer determines the best methods for freeing the ore from its gangue and combinations in order that it may be made useful in the arts; they require special knowledge in physics, chemistry, and metallurgy. These three functions sometimes are and sometimes are not exercised by the same individual. In the old countries the differentiation has become very decided; on this coast it is becoming more and more so every year.

This triple subdivision of the profession leads to a similar one in the educational work. Three distinct and more or less independent courses of study are recognized, in each of which the studies indicated above claim, respectively, pre-eminence; and that student only who has successfully completed these three lines of study, can claim to be fully conversant with the subject of mining in all of its details, at least so far as study alone can make him so.

All three of these courses are being developed in the Mining School as rapidly as the resources of the institution will permit, but it is to the course of mineralogy and geology that we wish to refer more particularly in the present article. Up to the present time, owing to lack of needed facilities, instruction has been given only in mineralogy and general geology. Courses of lectures are now to be added on petrography (treating especially of rocks as contrasted with minerals) and on economic geology (treating especially of ore, etc.), together with the necessary laboratory work in both branches. Opportunities for study and investigation in this course in the Mining School will hereafter be very complete.

The whole upper floor of the South Hall is being furnished and equipped for the work of this department. The large hall, 75 ft. by 25 ft., will contain the museums of mineralogy, petrography and economic geology. Handsome and commodious black walnut cases are being constructed for the extensive collections which have remained unpacked and inaccessible for so many years. The new cases are of the best design and are so arranged that both the systematic and the exhibition collections are combined in the same case, thus preserving the unity of the whole. Ample space is provided for all the material of the different museums now on hand, including the collections of the State Geological Survey, as well as for that which is continually being sent from all parts of the coast.

The Museum of Mineralogy, while specially rich in California minerals, contains likewise specimens from every quarter of the globe. The collection as a whole is arranged after Breithaupt's system, the specimens of each species of mineral being sub-arranged geographically. The exact geographical distribution of each mineral can thus be determined at a glance. When the collection is more complete this will develop many interesting relations concerning the laws of the distribution of gold, silver, copper, etc.

The Museum of Petrography will be arranged after the same general plan. When the work is completed a detailed description of all of the rocks of the State will be published. From the immense amount of labor involved in the preparation and study under the microscope of thin sections from so many hundreds of rock specimens, the work necessarily progresses slowly. When finished, a classification of the building materials and other rocks of economic use will be made, which will be of great practical value.

The Museum of Historical Geology will contain specimens of rocks, carefully arranged, to illustrate the geological structure of the earth's crust. Each sedimentary rock will be accompanied by its appropriate fossils, and the relation of igneous to sedimentary rocks will be carefully brought out. The possession of the

Geological Survey material renders it possible to illustrate the geological structure of California in great detail.

The Museum of Economic Geology will exhibit, by a full suite of specimens from each mine, the exact nature of the ore-deposits upon the Pacific coast. From each deposit will be displayed a specimen of each of the different ore minerals, of the veinstone, of the contact of ore and veinstone, of the selvage or gouge, of the country rock from foot-wall and hanging-wall, and of the contact of vein and country rock. In addition, specimens illustrating any other important geological feature of the deposit will be included—such as a change in the country rock, either in dip or strike, the intersection of two veins, "horsts," etc. The collection will not be confined to deposits of precious and base metals alone; all deposits of economic value, such as peat, coal, asphaltum, oil, sulphur, salt, gypsum, limestone, clays, etc., will be similarly represented.

In response to circulars which have been widely distributed over the coast, the material for this collection is continually coming in from the mines, and when completed it will be made the basis of an extensive series of investigations into the geographical and geological relations of the ore deposits of the coast, with a view of determining the laws of their occurrence and formation. The specimens will also be used for illustrating the course of lectures on economic geology, the students thus coming in direct contact and acquiring perfect familiarity with the identical ores which they will be called upon later to work.

We shall regard this collection, when complete, as by far the most valuable one, for this coast, in existence. It will be a complete record of the mining resources of the country; and the fact that it is the property of the State and is managed by competent scientific men ensures its permanence and its integrity. We wish it might be felt the duty as well as the pride of every mine owner on the coast to have his mine fully represented in this collection.

These museums are always open to the public, and an attendant is always present to conduct visitors through them. On the opposite side of the main hall are the mineralogical and petrographical laboratories, the museum work room, the instructor's private laboratory and the instructor's study.

The mineralogical laboratory contains a large collection of unlabeled minerals which the students determine by their physical properties. By this process of determination a knife, a lens and a small piece of biscuit porcelain, are the only implements required, together with the general knowledge of minerals which has already been acquired during the previous year's course. Students thus learn to determine all of the common ore, and rock-forming minerals at sight, and all except the rarer minerals, with the use of the above-mentioned instruments, such as can be carried easily in the vest pocket.

In the petrographical laboratory is to be placed for determination by the students a large collection of unlabeled rocks. The distinctly granular or macrocrystalline and macroclastic rocks will be determined by the ordinary processes of physical examination, while the compact or cryptocrystalline and cryptoclastic rocks will be investigated by the preparation of thin sections and subsequent study under the microscope. Every facility for the grinding and mounting of thin rock sections will be accessible to the student at all times. The instructor's private laboratory will be furnished with every facility for wet analyses, fusions, etc., a complete blowpipe outfit, a lapidary's lathe, with diamond saw for cutting and grinding thin rock and crystal sections, and mounting table for microscopic work.

Next to the laboratory is the private study, containing the instructor's special library and cases for the fine physical instruments used in the investigations of minerals and rocks. The renowned firms of Hartnack and Fuess in Berlin will furnish the optical apparatus. The equipment will contain microscopes specially constructed for mineralogical investigation; a very fine goniometer reading to 10 seconds, for the measurement of crystal angles, both at ordinary and at elevated temperatures; a polariscope for investigations in polarized light, determinations of indices of refraction in crystals, angle of optical axes, etc.; a spectroscope, with a battery of prisms of great delicacy; and one of Bunge's new short-arm chemical balances of great accuracy. Here will likewise be kept the large collection of mineral and rock sections used by the instructor for the illustration of his lectures in mineralogy and petrography.

It will thus be seen that this department of the State Mining School has become enabled, through the wise liberality of the last Legislature, to offer to all, "without money and without price," facilities for acquiring most thorough training in every department of mineralogy and geology; and in addition to the regular instruction every opportunity is presented, both to regular students and to qualified special students, for the independent investigation of any topic connected with either of these branches.

We cannot close this short sketch without noticing the generous liberality of Wells, Fargo & Co. in forwarding from any point on their lines, free of charge, material for the museums of the University. On account of the great expense of sending such heavy material over long distances, the growth of the collections would be materially retarded were it not for their kindness in this respect.

The Winged Phylloxera.

J. S. Hyde, of Santa Rosa, writes to the *Rural Press* that a few days since, while examining some grape-vine roots infested with the phylloxera, he remarked to some friends present that there was little danger from the rapid spread of this pest, as the insect, in its winged form, had not yet appeared. The words had scarcely passed from his lips ere one of the gentlemen cried out: "I see one with wings now!" On a more careful examination eight full-winged specimens were found; the next day four other specimens were discovered. Several of these insects were sent to Dr. Hilgard of the State University for examination.

The above announcement by Dr. Hyde is very interesting, and not the less so from the fact that the insects he sent to Prof. Hilgard, although truly a winged-form, were sterile, and

FIG. 1.

FIG. 2.

FERTILE AND INFERTILE FORMS OF WINGED PHYLLOXERA.

not capable of spreading the destruction which our vine-growers fear. In order to show the difference between the fertile and infertile winged forms, we have reproduced engravings from Prof. Riley's drawings of the phylloxera, which show clearly the distinction between the two. Fig. 1 is the fertile-winged female, which thus far has not been observed in this State, unless some of the insects retained by Dr. Hyde are of this form. Fig. 2 shows the outline of each of the five specimens received by Prof. Hilgard. It will be observed that in the fertile-winged female the abdomen is prolonged and that the body is about half as long as the whole insect wings included, and is of a tapering, rounded form. In the sterile, the body is rarely one-third the length of the whole, and the abdomen is abruptly contracted, as shown in the engraving. It would have been

tund form. It is 19 inches long, 9 inches around the body, has a thick tail like a kangaroo, and weighs two pounds. Its color is yellow, with clearly defined black scales one-eighth of an inch in diameter, resembling the marking of a butterfly. This peculiar appearance is said to be the model which the Aztecs followed in making their pottery. The Mexicans also have decorations after the same pattern, and the Indians of this coast certainly follow it in their basket-work. This specimen is very seldom seen and is known to be the rear guard of the past race of prodigious fauna represented by *dinosaurius*, *megatherium*, *pterodactyle*, etc. It is slow-motioned, cannot overtake its prey, and is consequently easily devoured by its enemies; hence, its liability to become extinct, which enhances the value of the few specimens in existence. The Indians regard the reptile as a great deli-

THE AZTEC LIZARD (*Heloderma suspectum*) FROM ARIZONA.

better if the engravings had shown the front view of each insect, but the different forms of the abdomen can still be clearly seen.

Concerning the finding of the sterile-winged form by Dr. Hyde, Prof. Hilgard spoke at the meeting of the Horticultural Society as follows: "After all the matter still rests pretty much as we conjectured it was two years ago. I then stated that either the winged phylloxera was not here at all, or in very small numbers. There are live or six varieties of the insect non-winged, which live on the roots, which produce a winged form towards autumn, which, like the wingless form, is simply a female which lays eggs without any connection on the part of the male. The winged female is simply an egg-layer, like the others. She lays a few eggs only. Some of these eggs produce males and others females. It seems to be necessary that there should be a kind of renovation of the race in that way. The winged insect is dangerous, of course, because it is capable of flying to some extent. In Europe the winged form has served to carry the insect a distance of 30 or 40 miles at one jump, leaving districts between unaffected. In Sonoma the progress of the pest has been slow, and it has been thought that the winged insect was absent. The winged forms produce only two varieties—one fertile, the other infertile. I understand that in other countries the proportion of infertile ones is small and that of fertile ones large. Of the eight sent me by Dr. Hyde, I find that five are of the infertile kind. I infer, therefore, from the evidence thus far produced, that the spread of the pest will still be comparatively slow, de-

pending upon the kinds that crawl instead of those that fly."

The announcement by Dr. Hyde will doubtless induce a still wider search for the winged insect. We shall be pleased to receive any specimens which may come to the eyes of our readers to determine their exact standing.

The Aztec Lizard.

Prof. J. G. Lemmon, the well-known botanist and naturalist, brought with him from his last visit to Arizona a living specimen of a rare reptile, called the Gila monster or Aztec lizard (*Heloderma suspectum*). The engraving on this page gives a good idea of the animal. The engraving is from a photograph by Williams & Samuels, cor. 11th and Clay Sts. Oakland.

The specimen is a female and is believed to contain many eggs, which would account for its ro-

Letters from the Comstock.—No. 6.

EDITORS PRESS:—There has just been concluded in Carson a suit in the U. S. Circuit Court, wherein the old Wells-Fargo mining company were conducting an action against the new Wells-Fargo company, verdict for the defendants. The history of this suit is as follows: About two years ago the Wells-Fargo was owned by a company headed by one Pearson, a character quite well known on Pine St. The principal business of the company consisted in levying and collecting assessments. What they ever did with the money is more than your correspondent can say. After being raked in from the public it became absorbed in some mysterious manner. Perhaps Pearson got some of the benefits of the same, and perhaps some of the Trustees; but how any one of the Trustees could have gotten any of it when Pearson was in sight is a grand mystery.

Presently people got tired of paying assessments for Wells-Fargo stock, and the delinquent lists got to be pretty long. One of them was advertised in the *Virginia Chronicle*, per order of Pearson, and the bill sent to him. No attention, however, was paid to this, and D. E. McCarthy, proprietor of the *Chronicle*, finally got his dander up and went for Wells-Fargo like a terrier for a rat. The first thing the Pearson crowd knew was that the mine was sold at Sheriff's sale to satisfy a claim of a few hundred dollars, and it was bid in by an agent of McCarthy. Everything was done decently and in order, in a legal sense; but the Pearson crowd, knowing that the mine had passed from their hands, kept right on levying assessments and collecting when they could. They brought a suit to recover the property and were beaten; they carried it from court to court, and although worsted at every turn, kept right on dragging their net up and down the street and getting what they could. The newspapers exposed the swindle and showed that there was no such thing as a Wells-Fargo Co. headed by Pearson and his gang; but the Board allowed the stock to remain on the list, and every day people who had no means of knowing the exact state of affairs were suffered to purchase for hard coin stock not worth the paper it was printed on. Now the last decision of the courts dispossesses Pearson of all the claims he made for the mine; but whether or not the Board will still allow the old Wells-Fargo stock to be sold through its official cognizance remains to be seen.

Pearson has been a sort of ulcer in the body mineral for years, and he never yet touched a piece of mining property that he did not hight it with crookedness and chicanery. There are scores of just such men in mining circles, and until they are unceremoniously thrust out the public will have precious little faith in mining.

Just now the bears are using every lever to depreciate north end stocks. The wires are loaded down with accounts of porphyry, barren ledges and failures to find ore. A careful reading of these dispatches shows exactly where the nigger in the fence is. Portions of the mine are spoken of as failures where no one ever expected to find any ore, and really truthful information is twisted into meaning a thousand things which have a bearish tendency upon the market. Besides this, brokers are pressing their customers for "mud," and the screws are being put on in every available way to help the depression. People can take these signs as they see fit. There is some object in it all, and those who let go at such a time will have themselves to blame. As for the mines themselves, there is nothing to be said of them now, which might not have been equally true a week ago. HAND DRILL.

MEETING OF MINING ENGINEERS.—We have received from Prof. Thomas M. Drown, Secretary of the American Institute of Mining Engineers, a circular announcement of the preliminary arrangements for the Lake Superior meeting of the members. The arrangements promise a large degree of pleasure to the engineers and their families. As for example: a steamboat will meet the party at Marquette, on which the members and ladies accompanying them will live during their stay in the Lake Superior region, and on which excursions will be made to various points on the lake, including the copper districts, Thunder Bay, Silver Islet, and, by the way of Sault St. Marie and the Straits of Mackinaw, into Lake Michigan. Further details respecting the route from New York, place of entertainment in Chicago, rate of fare, subsistence in the lake regions, etc., will be given in a subsequent circular. A postal card is sent with the first circular, on which those members who propose to attend the meeting are requested to fill the blanks and return the card to the Secretary as early as possible. Punctual attention to this request is necessary to the comfort of all concerned. The time fixed for the party to leave Chicago for Marquette is August 23d.

THE SOUTH AFRICAN DIAMOND FIELDS.—Advices received from Port Elizabeth state that the value of the diamonds exported from the South African diamond fields last year was \$3,685,610, as compared with \$3,084,711 in 1878.

"PASSED OVER."—Frank S. Weeks, a practical printer and writer, died of consumption, in this city, July 25th. Mr. Weeks came from Troy, N. Y., to California at the age of 18, and commenced his avocations as printer and contributor on the *Mt. Messenger* in La Porte, Sierra county, in 1862. Having pursued an honorable course, he has left many friends.

THE national debt decreased \$5,576,053 during July.

The Mechanics' Institute Fair.

The approaching fair of the Mechanics' Institute, which will be opened in the pavilion on the 10th inst., promises to be unusually interesting and attractive. The exhibitions of the Institute have always been characterized by a large and generous spirit, as shown in the systematic efforts to promote and advance the skill, taste, industry and products of the State; but it would seem to be the determination of the managers in the coming fair to surpass all their previous achievements. For this purpose they have earnestly invited the co-operation not only of all those in California who feel an interest in the advancement of its varied industries and products, but as well of the people of the entire coast. We do not doubt that the request will receive an efficient and liberal response; for apart from the palpable advantages that will follow a generous exhibition of the multifarious industries of the coast, the munificent offer of premiums in gold, silver and bronze medals, in diplomas, and in very hard cash, will be an additional and strong incentive. The list of premiums is so large and so valuable that we think it well worth the while to call special attention to it. Here are the details of the ample list: Cash premiums, 62; medals—gold, 40; silver, 313; bronze, 215; diplomas, 92. These handsome prizes will bear the super-scription of the Institute—the highest industrial authority in the State—and are worthy of a keen and generous competition. As awards of merit for some desired quality or valued excellence, they will give substantial character to the possessor; and besides the profit which they will bring directly or indirectly, they will be a lasting source of satisfaction and pride.

DIVISION 1.

MANUFACTURED PRODUCTS: MACHINERY.

CLASS NO. 1.—Steam Engines, Boilers and Appliances.

GOLD MEDAL.—For best Automatic Cut-off Steam Engine, not less than 15 horse-power.

SILVER MEDALS.—Best Portable Engine, mounted on wheels, for farm and general use; Straw-burning Engine; Vertical Boiler and Engine, Combined; Upright Engine (small); Horizontal Engine and Boiler Combined; Steam Boiler made in Cal.

BRONZE MEDALS.—Best Traction or Road Engine; Steam Engine (working model); Steam Engine Governor; Boiler Injector; Oil Engine; Gas Engine.

DIPLOMAS.—Best Low Water Indicator for Steam Boilers; Safety Valve for Steam Boilers; Tallow Lubricator for Steam Cylinders; Piston Packing; Best and Most Improved Grate Bar.

CLASS NO. 2.—Hydraulic Machinery and Steam Pumps.

GOLD MEDAL.—Best Steam Pump, direct and double acting.

SILVER MEDALS.—Best Water Elevator, by the Direct Action of Steam; Double Acting Lift and Force Pump for general purposes; Hydraulic Engine; Centrifugal Pump; Hydraulic Motor for Light Machinery; Hydraulic Lift; Hydraulic Lifting Jack; Turbine Water Wheel.

DIPLOMA.—Best Hydraulic Ram.

CLASS NO. 3.—Machinists' Tools and Metal-working Machinery.

SILVER MEDALS.—Best General Display of Articles in this Class; Iron Planer, in motion; Power Blower; Hand Belows; Power Punch.

BRONZE MEDALS.—Best Power Shearer and Punching Machine; Engine, Lathe; Shaping Machine; Turners for Furnaces or Forges; Milling Machine; Bolt and Screw Cutter; Power Hammer; Drilling Machine; Emery Wheel Machine; Taper Setter.

DIPLOMAS.—Best Portable Forge; Drop Press; Display of Machinists' Small Tools; Vices; Ratelut Drill; Shaft Coupling.

CLASS 4.—Wood-Working Machinery.

GOLD MEDAL.—Best General Display of Saws.

SILVER MEDALS.—Best General Display of Wood-working Machinery; Surface and Matching Machine, to plane not less than 24 inches wide; Portable Saw-Mill; Shingle Machine; Lathe for Irregular Forms, in operation; Dope-tailing Machine; Box Nailing Machine; Circular Saw with inserted teeth, Lathe Machine.

BRONZE MEDALS.—Best Band Saw for Lumber; Band Saw for Scroll Work; Reciprocating Saw for Scroll Work; Carving Machine; General Wood-working Machine; Molding Machine for Straight Molding; Molding Machine for Ornamental Moldings; Circular saw and Table Complete; Wood Lathe; Foot Lathe for General Purposes; Slide Lathe for Taper or Other Forms; General Display of Cutters for Wood-working Machinery; Saw Gunner.

DIPLOMAS.—Best Molding Machine; Sand-Papering Machine; Trenching Machine; Miter Sawing Machine; Foot Power Scroll Saw (in operation).

CLASS NO. 5.—Printing and Miscellaneous Machinery.

GOLD MEDAL.—Best display of Boot and Shoe Machinery.

SILVER MEDALS.—Best display of Printing Machinery; Type Gasting Machine; Paper Rolling Machine; Display of Stereotype Plates and Work; Windmill; Ice Machine; Gas Machine; Brick Machine.

BRONZE MEDALS.—Best Power Printing Press; Foot Printing Press; Paper Folding Machine; Pulley Blocks; Hand Printing Press; Lifting Jack, other than Hydraulic; Carpet Beater.

DIPLOMAS.—Best Tobacco Cutter; Meat Chopper, (power).

CLASS NO. 6.—Mining Machinery and Appliances.

GOLD MEDAL.—Best General Display of Mining Machinery.

SILVER MEDALS.—Best Stone Breaker and Ore Crusher; Rock Drill (actual test); Air Compressor; Quartz Mill; Amalgamating Pan (running); Concentrator (in operation); Quick Silver Furnace; Furnace for Roasting Ores; Apparatus for Transporting Ores; Perforated Quartz Screens.

BRONZE MEDALS.—Best Ore Feeder; Dump Car or Bucket; Hydraulic Nozzle and Joint.

CLASS NO. 7.—Laundry Machinery.

SILVER MEDAL.—Best Washing Machine.

BRONZE MEDALS.—Best Mangle; Wringer; Centrifugal Clothes Dryer.

DIPLOMAS.—Best Wash Boiler; Crimping Machine.

CLASS NO. 8.—Fire Apparatus and Appliances.

GOLD MEDAL.—Best Steam Fire Engine (actual test).

SILVER MEDALS.—Best Carbonic Gas Engine; Hook and Ladder Truck; Hose Carriage or Truck; Fire Escape.

BRONZE MEDALS.—Best Carbonic Gas Extinguisher.

DIPLOMAS.—Best Hydrant; Hose Coupling.

CLASS NO. 9.—Marine.

SILVER MEDALS.—Best Driving Armor and Appliances; Life Boat; Outrigger Shell Boat (Wood); Outrigger Shell Boat (Rau).

BRONZE MEDALS.—Best Life Preserver; Life Saving Raft; Model of a Sailing Vessel; Model of a Schooner; Captain's Ship's Windlass; Propellers.

DIPLOMA.—Best Disengaging Apparatus for Life Boats.

CLASS NO. 10.—Sewing Machines, Knitting Machines, Braiding Machines, and Looms.

GOLD MEDALS.—Best Over-Seam Sewing Machine; Sewing Machine for Manufacturing Purposes; Sewing Machine for Domestic Work.

SILVER MEDALS.—Best Loom for Weaving Carpet (in operation); Loom for Weaving Silk Cloth (in operation); Loom for Weaving Silk Ribbons (in operation); Loom for Weaving Woolen (in operation); Loom for Weaving Wire Cloth; Button-hole Machine.

BRONZE MEDALS.—Best Silk Weaving Machine (in operation); Family Knitting Machine; Braiding Machine.

CLASS NO. 11.—Agricultural Machinery.

GOLD MEDAL.—Best General Display of Agricultural Machinery.

SILVER MEDALS.—Best Reaper and Mower, with Self Raker, Self Binding, Grain Harvester; Thresher and Separator; Portable Hay Press; Fruit Dryer; Machine for Digging or Excavating; Steam Plow.

BRONZE MEDALS.—Best Reaper; Mower; Lawn Mower; Broadcast Seeder; Riding Cultivator; Sulky Hay Rake; Harrow; Str Plow; Gang Plow; Side Hill Plow; Plow for General Purposes; Horse Power; Cider Mill; Portable Mill for Grinding Grain; Hay and Straw Cutter; Stump Extractor; Artesian Well Boring Tools; Bag Holder; Burr Mill Stones; Seed Drill.

DIPLOMAS.—Best Assortment of Mower and Reaper Knives; Mower Knife Sharpener; Walking Cultivator; Corn Planter; Potato Digger; Fence for General Use; Bee Hive; Post Hole Digger.

DIVISION 2.

MANUFACTURED PRODUCTS: METALS.

CLASS NO. 12.—Iron, Steel and Lead.

GOLD MEDALS.—Best general display of Iron and Steel; Lead and its Manufactures; Wire and Wire Rope; Car and Carriage Springs.

SILVER MEDALS.—Best general display of Bolts and Nuts; Assortment of Wire Ornamental Goods; Assortment of Castings; Metal Signs; Embossed Signs; Work; Chains and Chain Work; Display of File Cutting, California make; Mattress Springs.

BRONZE MEDALS.—Best general display of Wrought Iron Pipe and Boiler Tubing; Horse Shoes, malleable Iron and Steel; Axes.

DIPLOMAS.—Best general display of Rivets; Cut Nails.

CLASS NO. 13.—Cooking, Heating and Ventilating.

(By request of exhibitors in this class no premiums offered for these articles): Best Hot Water; French Portable Family Range; Parlor or Office Stove.

SILVER MEDALS.—Best Cooking and Heating Apparatus; Coal Oil Cooking and Heating Apparatus; Best display of Tin Ware; Copper Ware; Janned Ware; Planished Ware.

BRONZE MEDAL.—Best Steam Heating Apparatus.

DIPLOMA.—Best Flat-Iron Heater.

CLASS NO. 14.—General Hardware.

GOLD MEDAL.—Best display of general Hardware.

SILVER MEDALS.—Best assortment of Fire-Arms; best Fire Arm, California make.

BRONZE MEDALS.—Best display of Bronze Hardware; best assortment of Fishing Tackle; Harness Ornaments; best Set of Carriage Tools; Metal Signs; Embossed Signs.

DIPLOMA.—Best Rubber Printing Wheel.

CLASS NO. 15.—Fire and Burglar Proof Safes and Locks.

GOLD MEDAL.—Best Fire and Burglar-proof Safe.

SILVER MEDAL.—Best Burglar-proof Lock; best assortment of Locks, California make.

CLASS NO. 16.—Cutlery and Edge Tools.

GOLD MEDAL.—Best display of general Cutlery.

SILVER MEDALS.—Best Carving Set; assortment of Edge Tools, California make.

CLASS NO. 17.—Grates and Mantels—Marbles, Artificial Stone, Earthenware, Glassware, Etc.

GOLD MEDAL.—Best display of Glass Ware (Cal. make).

SILVER MEDALS.—Best display of Marble Mantels; Marbleized Iron Mantels; best Single Stove; Marble Mantel; best assortment of Terra Cotta Ware; best Sewer and Drain Pipe; Ornamental Chimney Tops; best display of Cut Glass, Porcelain and Fancy Ware; Monumental Work.

BRONZE MEDALS.—Best display of Marbleized Slate Mantels; best Fire Orates; best specimen Artificial stone; Polished Granite; best Buckingham and Yellow Ware.

DIPLOMAS.—Best specimen of Fire Brick, not less than 10; Pressed Brick, not less than 20.

CLASS NO. 18.—Brass Work—Gas and Lamp Fixtures—Plumbers' Goods, etc.

GOLD MEDAL.—Best assortment of Brass Work.

SILVER MEDALS.—Best assortment of Belis; best display of Gas Fittings; best Decorative Single Work; best Galvanized Iron Work; Copper Work; best sample Galvanizing (done here); Electro-plating (done here); best Water Closet; Sewer Trap.

BRONZE MEDALS.—Best display of Plumbers' Goods; best assortment of Steam Fittings; best display of lamps; best Zinc Ornamental work; best Water Filter.

DIVISION 3.

MANUFACTURED PRODUCTS: WOOD OR WOOD AND IRON.

CLASS NO. 19.—Carpenters', Joiners', Carvers' and Stair Builders' Work—Ornamental Glass, Painting, etc.

GOLD MEDALS.—Best general display of Stained, Ground and Best Glass for Architectural Work; best Plate-glass Mirror (imported in California).

SILVER MEDALS.—Best specimen of Stair Building; best Newell Post, and not less than six Balusters; best specimen of Cut and Embossed Glass; best Wood Graining; Mirror or Picture Frame, design and workmanship; best Parquet Partouts; Wooden Mantel, style and finish.

BRONZE MEDALS.—Best Carving in Wood for Building Purposes; best assortment of Church Furniture; set of Inlaid and painted section of Car; best Double-hung Window; best assortment of Picture Frame Moldings; best display of Articles made from California Woods; Fancy Brackets and Ornaments; Composition Ornaments; best display of Turned Articles from California Woods; Weather Strips for Doors and Windows.

DIPLOMAS.—Best specimen of Scroll Sawing; Ornamental moldings; best Parquet Flooring, not less than 9x9.

CLASS NO. 20.—Musical Instruments.

GOLD MEDAL.—Best general display of Musical Instruments.

SILVER MEDALS.—Best Brass and Silver Wind Instruments; Stringed or Reed Instruments made in California; best display of Music Boxes.

CLASS NO. 21.—Vehicles and their Attachments—Children's Carriages, Hobby Horses, Etc.

GOLD MEDAL.—Best general display of Carriages.

SILVER MEDALS.—Best Horse Car; Hotel Coach; best Double Buggy; Single Top Buggy; Open Buggy; best Stage Coach, all Cal. make; best Platform Spring Double Wagon; Platform Spring Single Wagon; best Buggy Wheel; best Street Buggy; Car; best Double-hung Window; best Cart; Butcher's Cart; best display of Carriage Goods and Hardware; specimen of Carriage Blacksmithing; Bicycle.

BRONZE MEDALS.—Best Sulky, Cal. make; Farm Wagon; Wagon Wheel; best Child's Carriage; Hobby Horse; best Swing in operation.

CLASS NO. 22.—Furniture, Upholstery, etc.

GOLD MEDAL.—Best general display of Furniture.

SILVER MEDALS.—Best set of Parlor Furniture; Dining Room Furniture; Bedroom Furniture; Library Furniture; Office Furniture; best Extension Lounge or Sofa Bed; assortment of Chairs; best School Furniture; Office Desk; best specimen of upholstering; display of Chocolate, Cocoa and Shaded and Fictitious; Curtains, Cornices and Trimmings.

BRONZE MEDALS.—Best Easy Chair; Barber Chairs; best Spring Mattress; Metal Spring Bed Bottom; Slat Spring Bed Bottom.

CLASS NO. 23.—Billiard Tables.

GOLD MEDAL.—Best display of Billiard Tables, style and finish.

SILVER MEDALS.—Best Billiard Table; Billiard Tables, parlor use.

BRONZE MEDALS.—Best Billiard Table Cushions; Balls, Cues and Racks.

CLASS NO. 24.—Wooden Ware, Brushes, Wire Goods, Willow Ware, etc.

GOLD MEDAL.—Best display of Willowware.

SILVER MEDALS.—Best display of Willowware; Wire Goods; Brushes; Feather Dusters and Plumes; best display of Cooperage; California Manufactured Brooms.

BRONZE MEDALS.—Best assortment of Baskets; best assortment of Boxes, Butter Packages, etc.; display of House Furnishing Goods.

DIVISION 4.

MANUFACTURED PRODUCTS: ANIMAL AND VEGETABLE FABRICS.

CLASS NO. 25.—Boots, Shoes, Leather, Rubber Goods, etc.

GOLD MEDALS.—Best general display of Boots and Shoes (Cal. make); best general display of Harness and Saddlery.

SILVER MEDALS.—Best Ladies' and Misses' Hand-made shoes; Men's Hand-made Boots and Shoes; Machine-made Boots and Shoes; best Sole Leather; Fair Leather; Kid Leather; Morocco Leather; Calf Skins; Rawhide Goods; best Leather Hose, 100 feet, all Cal. make; best display of Rubber Goods; best assortment of Laid Cal. make; best Set of Harness; Saddle and Bridle; best display of Trunks and Traveling Equipage.

BRONZE MEDALS.—Best Leather Belting; Cotton or Linen Hose, not less than 100 feet; best display of Whips; Horse Collar; best Trunk for Traveling.

CLASS NO. 26.—Hemp Cordage, Paper, Furs, Hair, etc.

GOLD MEDALS.—Best general display of Cordage, Cal. manufacture; best general display of Paper, Cal. manufacture.

SILVER MEDALS.—Best Bale of Hemp, raised in Cal.; Bale of Imitation Silk, raised in Cal.; sample Ramie Fiber (dressed), not less than 20 lbs.; sample California Cotton, 20 lbs.; best display of Furs; display of Woods of this Coast; best Goat or Sheepskin Mats.

BRONZE MEDALS.—Best Bale of Excelsior; specimen Curled Hair; best general display of Paper Boxes; best display of Carriage Robes; samples of Furs Cleaned or Colored.

DIPLOMA.—Best general display of Paper Bags.

CLASS NO. 27.—Woolen Dress Goods Carpets, Cotton, etc.

GOLD MEDAL.—General display of Woolen Goods (Home manufactured).

SILVER MEDALS.—Best specimen of Cal. manufactured Dress Silk (25 yards); Ribbons (10 varieties); best samples of Cal. manufacture; best display of Carpet; best display of Silk Thread and Twist; Knit Goods (all Cal. make); best All Wool Cassimeres; Blankets; best All Flannel; best display of Carpets; Rag Carpets, style and quality; Mats and Matting (Cal. make); Oil Cloth, Cal. manufacture; Weaver of any kind; best display of Articles manufactured in the building from any of the above goods; Tents Awnings and Camp Equipage.

CLASS NO. 28.—Gentlemen's Furnishing Goods, etc.

SILVER MEDAL.—Best display of Gentlemen's Shirts, style and workmanship, Cal. manufacture; best display of Gent's Furnishing Goods; Dress Suit for Gents; Umbrellas and Parasols; best display of Gent's Hats and Caps; Gloves, Goat or Buckskin, (Cal. make) Gloves, Kid.

BRONZE MEDAL.—Best Business Suit for Gents; best display of Boy's Clothing; Military Goods; Regalia; Masquerade Costumes and Masks.

CLASS NO. 29.—Ladies' Furnishing Goods, Dresses, Cloaks, Millinery, etc.

SILVER MEDAL.—Best Ladies' Dress Suits (style and finish); best display of Ladies' Corsets (Cal. make); best display of Millinery and Straw Goods; of artificial Flowers; East India Goods, Shawls, etc.; Buttons and Fringes (Cal. make); Specimen of Work done at the Pavilion on any sewing Machine during the Exhibition.

BRONZE MEDALS.—Best Ladies' Walking Suits (style and finish); best display of Ladies' Corsets; best display of Underwear; display of Laces and Embroideries; Bonnet, style and workmanship; Ostrich Feathers, Plumes, etc.

DIPLOMA.—Skirt or Stocking Supporter.

DIVISION 5.

CHEMICAL AND NATURAL PRODUCTS.

CLASS NO. 30.—Tobacco.

SILVER MEDAL.—Best display of Tobacco, Leaf or manufactured; California manufactured Cigars, not less than 1,000.

BRONZE MEDAL.—California manufactured Cigarritos 6 varieties; Fine Cut Tobacco (Chewing); Fine Cut Tobacco (Smoking), all Cal. make.

CLASS NO. 31.—Chemical and Pharmaceutical Products.

GOLD MEDAL.—Best display and general assortment of Soap; assortment of Varieties and Artistic Materials of California manufacture; display of Paints, California manufacture.

SILVER MEDAL.—Best general display of chemical and Pharmaceutical Preparations; best assortment of Tinctures; best assortment of Compounds; best display of Candies (California make); Acids (California manufacture); best Flavoring Extracts and Essences; Gums (California make); Starch; Yeast or Baking Powder; Shoe Blacking (California manufacture); best display of Wines, Brandy and Ales (Cal. make); display of Matches, quality and variety (Cal. make); prepared Paints for general use; Printing Inks.

BRONZE MEDAL.—Best assortment of Staple Soaps; best display of Disinfectants and Antiseptics; best Flavoring Syrups; Lubricant; Yeast Preparations; best Soda Water Generating Apparatus.

DIPLOMA.—Best Natural Medicinal Water; best Soda Water Draught Apparatus; Soda Water Bottling Apparatus.

CLASS NO. 32.—Geology, Mineralogy, Zoology, Botany, etc.

GOLD MEDAL.—Best Mineralogical display; for the largest and most comprehensive Collection of the Natural Products of the Pacific Coast.

SILVER MEDAL.—Best display of Coals of the Pacific Coast; Salt, Rock and Ground; best collection of Ores and Crystals (Scientific); collection of Stuffed and Preserved Animals; Shells and Preserved Native Woods; Belles and Curiosities, gathered in any part of the World, of not less than 200 specimens; best display of Petroleum, Crude and refined, of California.

BRONZE MEDAL.—Best collection of Shells; Dried Flowers, showing their natural forms.

DIPLOMA.—Best collections of Insects and Oozocous; Fossils of this Coast.

DIVISION 6.

FOOD PRODUCTS.

CLASS NO. 33.—Groceries, Meats, Flower, etc.

SILVER MEDAL.—Best display of California Cured Hams, Bacon and Lard; California Refined Sugars; California Butter and Cheese; best assortment of Crackers and Cakes; assortment and quality of Canned Fruits, Meats and Vegetables; Jellies, Jams and Preserves; best general display of confectionery; display of Chocolate, Cocoa and Syrup; Wheat Flour; best Corn Meal; Buckwheat Flour; best assortment of Pickles and Sauces; best Fine and Fancy Candies; display of Canned Fruits, home made; collection of Jellies, home made.

DIPLOMA.—Best Lard Candies.

DIVISION 7.

LIBERAL AND DECORATIVE ARTS.

CLASS NO. 34.—Wines.

Best general display of California Wines; Sparkling Wine; Still Wine; Dry White Wine; Sweet Wine; Port Wine; Claret Wine; Older Wine.

CLASS NO. 35.—Liquors and Fermented Products.

SILVER MEDAL.—Best Brandy (Cal. Grape) Bitters; Ale; Lager Beer.

BRONZE MEDAL.—Best Whisky.

DIVISION 8.

FINE ARTS.

CLASS NO. 41.—Paintings in Oil and Water Colors.

One thousand dollars in cash will be awarded in this Class for the most meritorious Exhibits by our Local Artists. The classification of the awards not yet determined upon.

CLASS NO. 42.—Ceramic Art.

SILVER MEDALS.—Best Collection of Specimens of Ceramic Art; Specimen of Painting on Pottery by a Local Amateur (not less than 12 pieces); Specimen of Painting on Porcelain by a Local Amateur (12 pieces); Specimen of Pottery; Single Specimen of Painting on Porcelain; Collection of Decorative Art in Oil or Water Colors (other than Ceramic); Display of Encaustic Tiles.

BRONZE MEDALS.—Second Best Collection of Specimens of Ceramic Art; Specimen of Painting on Pottery by a Local Amateur (not less than 12 pieces); Second Best Painting on Porcelain by a Local Amateur (12 pieces); Second Best Single Specimen of Painting on Pottery; Second Best Single Specimen of Painting on Porcelain; Second Best Collection of Decorative Art in Oil or Water Colors (other than Ceramic).

CLASS NO. 43.—Sculpture, Statuary and Carving.

SILVER MEDALS.—Best Display of Marble Statuary; Display of Plaster Statuary; Specimen of Marble Statuary; Specimen of Modeling in Plaster; Seal Engraving; Wood Carving; Display of Ivory Goods; Display of Amber and Meerschmum Goods.

CLASS NO. 44.—Engravings, Original Drawings, Penmanship, Etc.

SILVER MEDALS.—Best Specimen of Wood Engraving (done here); Specimen of Lithographic Design; Original Pen Drawing; Original Crayon Drawing; Original Architectural Drawing; Original Pen Drawing; Specimen of Penmanship; Drawing, Strictly Perspective; Original Mechanical Drawing by an Apprentice; Mechanical Drawing by a Pupil of the Public Schools; Architectural Drawing by an Apprentice; Architectural Drawing by a Pupil of the Public Schools.

DIPLOMA.—Best Steel Engraving.

For Drawings exhibited by pupils of the Public and Private Schools of this City a liberal number of Bronze Medals and Diplomas will be awarded.

Metallurgy and Ores.

Nevada Metallurgical Works,
No. 23 STEVENSON STREET.
Near First and Market Streets.

Ores worked by any process.
Ores sampled.
ASSAYING in all its branches.
Analysis of Ores, Minerals, Waters, etc.
WORKING TESTS MADE.
Plans furnished for the most suitable process for working Ores.
Special attention paid to Examinations of Mines; plans and reports furnished.

E. HUBB
O. A. LUCKHARDT,
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS,

Mine and Mill Supplies,

CHEMICAL APPARATUS AND CHEMICALS, DRUGGISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17 California St., San Francisco.

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Muffles, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.
Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing those supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

**W. BRUCKNER'S
ROASTING FURNACE
AND
Ore Pulverizers.**

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.

The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps. Furnished also in sections for packing.

For circulars and prices apply to

Machinery.

GOLD AND SILVER

**Grinding and Amalgamating
MACHINERY.**

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorinating Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

**Wrought-Iron Frame
FOR STAMP MILLS.**

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Old Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc. Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,550.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Old and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

MOREY & SPERRY,

No. 145 Broadway, - NEW YORK.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph.D., M.E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, each, Mulay, jig, drag, circular, cylinder and hand Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, sawing, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

A Card from Architects.

**The California Architect and
Building Review.**

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city: Believing that a journal of this kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review" we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Huerns, John Marquis, B. McDougal & Son, Wm. Mooser, Wm. Curlett, Meeker & Banks, W. O. Hoagland, S. & J. Newsom, B. Hendrickson

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING JULY 27TH, 1880.

230,526.—RAIL JOINT FOR BED FRAMES.—W. B. Cantrell, Yreka, Cal.

230,413.—UNITING THE TWO HALVES OF CYLINDERS.—W. T. Carratt, S. F.

230,556.—EYE-SHADE.—W. Lancaster, Santa Rosa, Cal.

230,557.—REIN HOLDER.—A. Lay, Oakland, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions rendered upon patent cases in litigation, for the benefit of our readers:

DECISIONS OF THE U. S. COURTS.

The Peck, Stow & Wilcox Co. vs. Lindsay Sterritt & Co.

U. S. Circuit Court, Western District of Pennsylvania. Decided, November term, 1879; Acheson, J.:

1. The first claim in Reissued Letters Patent, No. 8,866, granted August 19, 1879, to the plaintiffs, as assignees of Amos Shepard, is valid.

2. The decision of the Patent Office upon the question of priority of invention will be binding upon a party and his privies where it appears that such party has filed in the Patent Office an application which had been placed in interference with the application of the original patent upon the reissue of which suit is brought, and had received and acquiesced in an adverse judgment of priority of invention, and had disclaimed the invention at issue in the interference which is also that involved in the suit for infringement, and had taken out a more limited patent.

3. Such decision cannot bar the defense of prior invention by others; but the action of the Office in granting the patent and the *prima facie* case made thereby, should have great weight where the matters set up in such defense were known to the party under whose patent the defendants claim title at the time of making his application, and that a claim was made by him notwithstanding the invention for the infringement of which suit is brought.

Strobridge vs. Lindsay, Sterritt & Co.

U. S. Circuit Court, Western District of Pennsylvania. Decided, May term, 1879; Acheson, J.:

1. The first claim of Reissued Letter Patents, No. 7,583, granted to Turner Strobridge, March 27, 1877, for an improvement in coffee-mills, is valid.

2. The mere fact that the device of the defendants has a function additional to that accomplished by the patented invention will not justify the defendants in the use of the latter without liability.

3. Letters Patent, themselves *prima facie*, establish the fact that the patent of the inventor is established thereby, and strongly confirmatory of this will be evidence tending to show the favorable acceptance by the public of the improvement and its recognition by the trade as something new and meritorious.

* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

REIN-HOLDER.—Anson Lay, Oakland, Cal. Patented, July 27, 1880. No. 230,557. Many different devices have been arranged for holding reins when the drivers of vehicles were absent. Among them are several clamps fixed to the dash-boards by rivets, bolts or otherwise, and intended as fixtures. In connecting them holes have necessarily to be formed in the dash-board. If they are moved from one place to another the holes remain and give an unsightly appearance to the dash. Some of the devices are furnished with spring clamps, these springs being attached to the holder by bolts or rivets and liable to be broken off. This present invention is intended to overcome these objections, as it may be secured in any place without bolts or rivets, and be moved from one side to the other at will. It consists in forming or stamping in one piece a rein-holder, spring and clamp, said clamp being made elastic so as to be secured to the dash-board or any desired point without the use of bolts or rivets or the necessity of perforating the dash-board.

POCKET MAPS.—We have received from Rand, McNally & Co., Chicago, copies of two pocket maps—one being a new sectional map of the State of Colorado, and the other a map of the "Dolores mines," situated in Pioneer district, Ouray county, Col. The latter map was compiled from actual surveys by J. F. Wannemaker, United States Deputy Surveyor, and William Munroe, Civil and Mining Engineer, Silverton, Col. The map of the State of Colorado is so indexed that every railroad, town, county, lake or river can be readily found. Both maps are well executed and substantially covered.

DITCHING AND DREDGING MACHINE.—John A. Murray, Stockton, Cal. Patented July 20, 1880. No. 230,329. This device consists in certain details of construction by means of which mud or earth is removed from the ditch and deposited at a distance therefrom, the operation being continuous. It also consists in providing buckets or scoops, having peculiarly arranged bottoms, which open and close automatically at the proper time, so as to drop the loads freely and rapidly.

ORE FEEDER FOR CRUSHING MILLS.—Joseph O. Mortz, S. F. Patented July 13, 1880. No. 229,903. This feeder consists in providing a cylinder or conveyor, in which is a piston or plunger, placed below a hopper, and so connected with an operating lever and weight or spring that the action of the stamp and operating lever will cause a reciprocating motion of the plunger, which will feed the ore forward to the battery by a direct action, in combination with a spring check-bar, by which lumps or masses of ore are retained and prevented from falling suddenly into the battery.

VALUE OF THE CARP FOR FOOD.—Some four years ago Prof. Baird engaged in the work of introducing in this country the best varieties of European food fish. A number of young carp, of the varieties known as the "leather carp" and the "minor carp," were imported, and in 1878 120 of these fish were removed to the Government carp ponds at the national capital, constructed especially for the purpose on the Washington monument reservation. The ponds cover about 12 acres, and the carp have multiplied to such an extent that it is possible now to begin the work of distributing them. The introduction and domestication of the new food fish will be of much interest and importance to all inland communities, as there is not a ditch, mill-dam or any hoggy, muddy spot which can not be converted into a pond in which they will thrive. The carps soon become tame and can be readily handled, and it is thought that in a few years they can be made as common an article of food as ducks or pigeons. Prof. Baird says that each of the female carp taken out of the pond will furnish from 250,000 to 1,000,000 of eggs, and by the artificial system of propagation, which insures the fertilization of all the eggs, 90% of them will be hatched.

A HANDBOOK OF SOUTHERN IDAHO.—A map of southern Idaho and adjacent regions, by Judge W. F. Anderson, of Bonanza City, accompanied by a fresh and interesting compilation of the most trustworthy data relating to the material resources of the Territory, by Charles Drayton Gibbs, M. E., has been laid upon our table by the publisher, Warren Holt, 717 Montgomery St. Judge Anderson's map is the result of a painstaking sifting and use of the most authentic materials in existence, and it will doubtless prove a trustworthy guide to the rich mining regions of southern Idaho. The compilation by Mr. Gibbs is chiefly derived from the local papers, from Judge Anderson, and from Prof. Hayden's geological survey of the Territories, and will be of especial value to the immigrant, the miner, and the capitalist. A careful reading of the little book will leave the impression that the phrase, "Gem of this Mountain," was fitly applied to that delightful and tssaming Territory.

WOMEN AS SANITARIANS.—In the course of his recent address at the Smith College commencement, President Gilman remarked: "That education must be secured through good living, obedience to the laws of health and recreation. The housewife should be educated so as to be able to prevent the ailments of those who dwell under the same roof with her. As every young man must expect to qualify himself to support a household, so must every young woman strive to render herself fit to manage the affairs of the house. The relations to each other of all the things which effect good living must be understood—food, air, water, exercise, etc.—in order that all emergencies may be provided for. All those things which we call modern improvements—gas, water-service furnaces, books, newspapers, magazines, and other manifold accessories of the household—must result in bad odors, noxious gases, headaches, and a host of other ills, unless their right use is understood and insisted on by the ever-watchful housewife. All sanitary reforms must rest on the shoulders of the women of the country."

GOOD NEWS FROM BODIE.—We learn that a mill has been started to crush ore from the Belvidere mine. This will be the first ore yet reduced from that property. There is also the good news of a co-operative effort on the part of the Bodie Con. and the Mono companies who have joined to sink a new and spacious shaft of three compartments. Better still, is the important news that ore has been discovered in the 600 level of the Jupiter. This is the greatest depth yet reached and in which ore has been found in any mine in Bodie, and the discovery is, of course, hailed as a good indication. Depth will certainly put Bodie in good form.

BRAKES ON ENGLISH RAILWAYS.—British railway seem to have made even less progress in the adoption of continuous train brakes than our own, says the *Railway Gazette*, in spite of parliamentary requirements. It appears that only 25% of the engine and 28% of the passenger train carriages are fitted with any of the systems returned by the companies as continuous brakes, and that many of the brakes so returned failed to comply with the conditions laid down by the board of trade. In this country brakes filling all these requirements are in use on the passenger trains of nearly all important roads, and earnest effort is being devoted to perfecting a continuous brake for freight trains.

The Lost Mines of Canma.

A late dispatch from New York says: Major Crossman has telegraphed from Panama, on his return from the "Lost Mines of Canma." The investigation does not appear to have been favorable.

A gentleman now on the Comstock once spent some time in search of those or some other lost mines in that region. He was so far successful that he found in this jungle an ancient road paved with stone. Trees three feet in diameter were in many places found growing in the center of this road, and the jungle was so thick and so tangled with vines, that in tracing the road it was necessary to cut a trail with machettes.

In this manner the old road was traced for many miles till it at last came to the edge of a great swamp. On the border of the morass it was squarely broken off. No sign of a road could be found in the swamp, but it was thought that its disappearance in such a place was of little moment. Our explorer was sure he would find the continuation of the road at this base of the mountains on the opposite side of this swamp, but nothing more of it was ever seen, though many days were spent in searching for it.

According to native tradition the road led to a ruined town where there were mines immensely rich in gold. On the seacoast were ruins of a town, and it was from these that the great paved road led out into the wilderness. In the forks of a tree, some 60 ft. from the ground, near the ruins of the town on the seashore, were seen about a wheelbarrow of bricks. The supposition was that these bricks had been brought to the place as ballast by some ship. The tree had grown up through a pile of them, carrying upward as it grew those seen in its forks.

At intervals along the road were found the ruins of what appeared to have been wayside stations. The low stone walls still stood, but no sign of roof or wood work of any kind remained, and great trees frequently grew within the enclosures, and in some places had overthrown one or more of the walls. In digging for relics on the floors of some of these old guard-houses fragments of charcoal or charred wood were found, but nothing in the way of tools, pottery or anything else of the least value.—*Territorial Enterprise*.

POPULAR SCIENCE MONTHLY.—The number for August of this sterling monthly of popular science presents a full list of instructive and entertaining paper from disciplined thinkers and writers. The opening paper on "The Ksarney Agitation in California," by Henry George, is a vigorous exposition of some of the present phases in the working of the political and social institutions of the country. The subject is treated with great care and power, and is entitled to an attentive reading. The delightful essay by M. Radau on "The Interior of the Earth," is completed. Prof. Huxley has a paper on "The Method of Zadig," relating to retrospective prophecy, which exhibits the writers characteristic traits. "Geology and History," by Prof. Grant Allen, ranks among the impressive and valuable papers. Two articles on natural history, under the titles of "Types of the Nubian Race," and "The Cinchona Forests of South America," will be found readable. Mr. G. B. Halsted's paper on "Algebras Spaces Sogies," is a remarkable report on the higher sciences; and Miss E. A. Youman's description of Prof. Rains' method of teaching chemistry in public schools, is interesting. There is a pleasant sketch by Prof. Joy of the veteran chemist, Frederick Wohler, whose 80th birthday is to be celebrated next month. Besides these principal papers there are several excellent popular science articles. And the editor's special work in editorials, notices of books and miscellany is fresh and complete. This valuable monthly of popular science is edited by one of the most remarkable men in America; and we cannot do a better service to young men especially than advise them to read it regularly. Its study will elevate their thoughts and help them to reflection, and will gradually lead them to systematic and higher methods. The *Popular Science Monthly* is published by D. Appleton & Co., New York city, at \$5 a year, or 50 cents a copy.

MINES OF SOUTHEASTERN NEVADA.—We learn from the Bodie *Standard-News* that Col. Ellsworth, a resident of that district, had just returned from a trip to Deep Spring valley, and what is sometimes called "Death" valley, in the southeastern part of Inyo county, where he reports an extensive mining region. Those valleys are about 160 miles from Bodie; their altitude is considerable, and the climate temperate. The surrounding hills are mineral-bearing. A conspicuous feature of Deep Spring valley is a mountain of chloride of sodium, containing enough pure salt to supply the continent. Copper ore abounds, and the ores of silver and gold are plentiful. In Deep Spring valley a limestone ridge extends four or five miles, and is apparently a mass of iron ore. A short distance to the eastward is Lida valley, another promising mining district. Two quartz mills are running there; and Col. Ellsworth asserts that the district is rich in various minerals. He believes the region to be an inviting one for the prospector and capitalist.

News in Brief.

THERE are 14 twins in one ward in Nashville, Tenn.

A LONDON lady had \$4,000 worth of flowers at a party.

INDIA'S yield of tea is estimated this year at 70,000,000 pounds.

FORTY-four horses were burned, August 1st, in Whits Sulphur Springs, West Va.

A SCHEME has taken shape for holding an international exhibition in Rome in 1885.

In an encounter in Chicago August 1st, Wm. Mackin fatally shot his brother Michael.

SIR BARTELE FRERE has been removed from Poultry is rapidly fattened for market in France on barley and steamed yellow carrots.

the Governorship of the Cape Town Colony.

FORESTVILLE, Sonoma, has had seven or eight distinct earthquake shocks this week and last.

A PRISONER in the jail in Fremont, O., has been identified as Bender, of infamous notoriety.

THERE has been a general increase in farm wages all over the country during the past year.

VICTORIO's band has been repulsed in an attempt to cross into the United States from Mexico.

At a riot in Victoria, Brazil, on the 28th ult., the troops and police fired on the populace, and killed 20 persons.

A NATURAL cavern, 600 ft. long, and others of less size, have been discovered near Wells, Somerset, England.

THERE is more building now going on in Tucson, A. T., than at any other time in the history of the city.

A TRACT of 50,000 acres on the Northern Pacific railroad has been bought for a colony from Belfast, Ireland.

THE Rumpa rebellion in Hindostan shows no sign of collapse, as the British troops cannot endure the unhealthy climate.

JOHN GIBBONS, a stage-driver, accidentally shot himself through the heart with a revolver at Milton, Calaveras county.

THE chief travel to the top of Vesuvius by the new railway is done by night to see it illuminated by the electric light.

Doc. HAMILTON, a railroad brakeman, was run over by eight cars at Independence, Oregon, July 29th, and instantly killed.

THE German revenue falls below expectations, and the Ministers are trying to invent new means for increasing the taxes.

THE Philadelphia *Times* says that everybody who bathes in Philadelphia water is obliged to take another bath to wash this mud off.

THE Baltimore schooner *George Washington* was searched by officers from a Spanish vessel off the east coast of Cuba on July 6th.

An Eureka, Nev., July 30th, N. A. Chandler, a well-known citizen, shot and killed himself. Financial embarrassment was the cause.

TENNESSEE has established a yellow fever quarantine against New Orleans, and Kentucky, Mississippi and Arkansas may do the same.

JOHN WILLIS, night clerk in a hotel at Helsinki, M. T., was attacked by a desperado and his companion, and was badly cut about the head.

A PARTY of Eureka sportsmen went out on Humboldt bay one day last week and managed to hook 700 rock cod, besides a number of halibut.

In London parasols get larger and larger. In some cases it is said there is no distinction in size between a parasol and the family umbrella.

THE right to hold a City Court in Los Angeles under the Constitution has been raised in the case of a Chinaman tried for violating the license law.

COMMON sense is getting ascendancy in the matter of children's shoes. Fewer little girls are seen with the high heels, which spoil their feet and their gait.

A DAUGHTER of Secretary Thompson, while out riding at Mare Island on July 27th, was thrown from a runaway horse, but fortunately escaped uninjured.

The Gatling gun is said to be surpassed in deadliness by a Swedish invention, which has been adopted by the Prussian navy, and can be carried into the mainport.

Or the 671 artists' models in Paris, 230 are Italiane, 120 French, 80 Germans, 60 Swiss, 49 Belgian, 45 English, 30 American, 3 Austrian, 2 Portuguese and 1 Irish.

In PARIS three francs are given to poor people for each child brought to the dispensary to be vaccinated, in order to induce parents to permit the operation.

A GENTLEMAN in Ulster county was married without knowing it. At least he is claimed by a young lady as her husband, and she shows a certificate confirming her statement.

THE old-fashioned leather fan, which was such a conspicuous feature of a lady's dress in the time of "good Queen Bess," has recently been revived under different names.

A FRENCH gentleman who tried to fast for 30 days, abstaining from all drink as well, died on the 21st of July, no amount of medical skill being adequate to restore his wasted vitality.

THE jury in the *Seawanhaka* case find that the disaster was caused by the bartering or collapse of one of the taps of the starboard boiler, whereby the flames were drawn under the gate-hinge into the fire-room.

FORTY-FIVE freight trains, comprising 1,500 cars, almost all of which were filled with grain, passed south on the Hudson River railroad Saturday, July 31st. It was the heaviest one day's shipment since the road was built.

The Mechanics' Fair Daily.

FAIR OPENS AUGUST 10, 1880.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the ELEVENTH VOLUME of the MECHANICS' FAIR DAILY during the FIFTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Tuesday, August 10th, 1880.

It will be of good size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resources and rapid progress of our great Western Community.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle by those who receive it freely at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive advertising and printing privileges, and will receive no advertising in the official catalogue and reports.

Our ten previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a more broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our coast.

DEWEY & CO., Publishers.

Also, publishers of the MINING AND SCIENTIFIC PRESS, No. 202 Sansome street, N. E. corner Pine, San Francisco.

By Universal Accord,

AYER'S CATHARTIC PILLS are the best of all purgatives for family use. They are the product of long, laborious and successful chemical investigation, and their extensive use, by physicians in their practice, and by all civilized nations, proves them the best and most effectual purgative Pill that medical science can devise. Being purely vegetable, no harm can arise from their use. In intrinsic value and curative powers no other Pills can be compared with them, and every person, knowing their virtues, will employ them, when needed. They keep the system in perfect order, and maintain in healthy action the whole machinery of life. Mild, searching and effectual, they are specially adapted to the needs of the digestive apparatus, derangements of which they prevent and cure, if timely taken. They are the best and safest physic to employ for children and weakened constitutions, where a mild but effectual cathartic is required.

FOR SALE BY ALL DEALERS.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and rather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

How to STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretensions claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

Office, No. 230 California Street,

San Francisco, Cal.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or band feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

DEWEY & CO.

SCIENTIFIC PRESS PATENT AGENCY.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered some inventors by other Agencies. Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

OXYGEN.

What is it? Everybody knows it is as essential to life as food itself. Yet when people are ill for the very want of revitalization through respiration, they dose themselves with drugs and bitters to the effect of demoralization! All Invalids should read **Drs. STARKEY & PALEN'S (Phila.) Treatise on Oxygen**, which is sent free to all who may ask for it. The subject is worthy of investigation. References to physicians in San Francisco, who use and prescribe Compound Oxygen in practice. As prepared for home use (conveniently sent to any address) it may be obtained of H. E. MATHEWS, 606 Montgomery street, S. F., upon the same terms as furnished by Drs. Starkey & Palen, Philadelphia, Penn. Complete instructions with each package.

Training of Apprentices.

The address delivered by President Cornwall at the opening of the Industrial Exhibition, held under the auspices of the Mechanic's Institute, is entitled to the most serious consideration. After giving a brief history of the beginning and growth of the Mechanics' Institute in this city, the details of which are especially interesting, Mr. Cornwall said: "Among other things now in contemplation by the patrons and friends of the Institute, to increase its usefulness, is the establishment of an apprentice's department, where regular and frequent meetings of apprentices may be had for the purpose of investigation and debate upon mechanical and other subjects, and the institution of a system of lectures and classes for technical education, where skilled workmen and learned teachers may explain the methods by which the hard things of life are made easy, the confused clear, and the doubtful certain. By these and kindred means, the increasing thousands of idle youth growing up in this city, many of whom, because of idleness, are drifting into vicious ways, may be diverted into channels of intelligent mechanical industry, and grow into useful and respected citizens, with happy homes, thus adding to the aggregate wealth and prosperity of the country."

This contemplated addition to the Institute is the suggestion of good, practical sense. The want of such a department for apprentices is as clear as the sun at noonday. There is no more important duty than the proper training in some study of physical science of the lads who are to become the artisans of the State. Every fact that the lad acquires, every principal that he understands, will equip him so much the better for his path in life in whatever direction it may lead. He will be immensely better in every respect for the mental discipline which it is proposed to give him. He will become not only a more intelligent and skillful workman, but he is likely also to become a better citizen. The young man to whom "the hard things of life have been made easy, the confused clear, and the doubtful certain," starts out in life with a certain assurance of "getting on." There is hardly one of our trades, except the merely huckstering ones, in which some kind of training in some branch of natural knowledge will not be directly profitable to the pursuer of that occupation. And as our various mechanical and artistic industries reach higher stages of development—as their processes become more complicated and refined, and competition at the same time becomes more keen—science will be invoked to aid the competitors, and the artisan who can best avail himself of her help in producing the most skillful work will come out uppermost in the contest. The advantages which would result from the establishment of such a school of training as that indicated in the address of President Cornwall are too obvious to require mention. Indeed, the wonder grows that an institution of the kind had not been established long ago.

Yet there are some who object to the "apprentices' department" on the ground that there is neither demand nor room for more mechanical labor; that our market is already plethoric and glutted; and finally, that we cannot enter into successful competition with the mechanical products of the manufacturers of the Atlantic seaboard. To these objections it may be answered that, if they are well founded, the very best thing for our manufacturers and artisans to do is to "shut up shop." But, happily, the Institute is animated by a larger faith in the future of this city as a great manufacturing center. For the President's address fully meets the objections. It suggests that the difficulty in the way of our manufacturers may be traced to the want of better methods, to the want of close and systematic economy—

wants which are essential to success in any enterprise. But as things exist the patience, intelligence and skill of San Francisco's mechanics have driven out of the market many wares of Eastern and foreign product. President Cornwall easily shows that the extension of the railroad system which is now progressing will throw open a vast field to the industrial enterprise of this metropolis.

We hope the beneficent suggestion of President Cornwall will be fully carried out, and that it will be in successful form before the next exhibition occurs. It is a happy idea to mend the training of our apprentices. We shall have more skillful because more intelligent mechanics, and the products of our shops will show higher excellence. The proposed school for apprenticed lads is of more importance to the welfare of the people than any radical political measure that could be thought of. There is a system of similar schools for the technical training of young artisans throughout England and parts of Ireland, and, as we learn from high authority, the effects are palpable, large and good.

DEPOSITS OF CHALCEDONY.—Extensive deposits of a variety of chalcedony have been discovered in the hills at the head of Huasna creek,

Lyon's Grain Cleaner.

We present on this page an engraving of a new grain cleaner of California design and manufacture. Its length is about 14 ft., and its extreme height nearly 8 ft., and its weight is a little over 4,000 lbs.

When in operation the larger elevator on the left is lowered to the ground, and the wheat is put into the hopper near the lower end. It is then carried up and discharged into the hopper on the top of the machine, from where it passes over a great number of large screens, having a rapid and short vibration endwise, and finally comes out pure wheat, all the barley, cheat, mustard seed, white caps and other foreign matter having been separated from it, and carried into compartments by themselves. The smaller elevator returns for recleaning the wheat which gets carried over with the tailings, as they are termed. A blast of air from the fan carries off all the light matter.

The distinguishing feature of this machine is the great number and area of its screens, thus allowing the wheat to pass over them in a thin sheet and to continue upon them for a period longer than usual, and until everything is taken

The Spenceville Copper Mines.

We learn from a late issue of the Nevada City Transcript that the copper mines at Spenceville are destined to become a conspicuous feature of the mining industry of Nevada county. In addition to the copper property mentioned, which is now shipping to this city ingots of marketable copper, and is on a paying basis, another copper mine, known as the American, situated about three miles above Spenceville, is looming up with great promise. The mine was visited lately by the editor of the Marysville Ledger, who has published some interesting details of the works. The mine was located by Mr. Bitner in 1876. There are two claims, each 1500 ft. long and 600 ft. wide; besides these, there is a tunnel claim 3,000 ft. long and 750 ft. wide. This tunnel will cut a series of four parallel veins. The surface croppings indicate that the southern vein is 108 ft. wide. The only ones that have been worked are the two northern; and they have been traced nearly their entire length by means of shafts. Both of these veins have been cut by a lateral drift and are now open. One of the northern veins assays 30% gold and a workable percentage of

copper. The gangue matter is quartz, through which the metallic grains are thickly distributed. The ore of the other vein is a rich-looking copper, which yields by assays from 10% to 70% of that metal. It is believed that each of these veins will develop a width of 70 to 90 ft. Heretofore only that quality of ore was sought that would pay for shipping; but lately Mr. Holland, one of the owners of the property, has roasted the ore very successfully. His process is simple. After a ten days' roasting of the ore, he leaches it in an old-fashioned hopper, the strong copper solution being caught in a wooden tank. It is then lead into a wooden trough and heated, and old scrap iron is introduced. The copper cement collects upon the iron, from which it is freed and cleaned. It is then ready for the market. These simple and inexpensive works have a capacity of about 50 pounds per day; they expect to extend them shortly to a daily yield of one ton. The owners have a process, which they will soon introduce, from which they believe a large economy will result both in time and money. Other owners of copper mines in the locality are trying the simple means for producing the cement which we have described, but we have no accurate returns of the results as to production and cost.

HUMBOLDT REDUCTION WORKS.—These reduction works, says the Silver State, are to be repaired and started up immediately. This news will be hailed with joy by many prospectors and mine owners in this county and along the railroad east and west of Humboldt. Since the works were closed down, owners of mines on which there are no mills have been obliged to assort their ores to a high grade and ship them to Salt Lake or San Francisco at a great expense. This has been very detrimental to the mining interests of this county and discouraging to prospectors, as ore that did not assay at least \$150 to the ton would not pay the expense of shipping them nearly 500 miles to reduction works. Henceforth there will be no necessity for this, as the most refractory ores, as well as the freest ores, can be worked here. Ores in any quantity, from a cack to a 1,000 tons, will be sampled upon its delivery at the mill and paid for in gold coin. The works will be thoroughly repaired and put in first-class order at once, so that miners who have ores on their dumps can convert them into coin by shipping them here at their earliest convenience.

THE President will leave Washington for California about Sept. 1st.

A NEW GRAIN CLEANER OF CALIFORNIA DESIGN AND MANUFACTURE.

about 25 miles from San Luis Obispo city. The Tribune describes the variety as agate, and says the deposits or quarries have been sold to Kessler Bros., the proprietors of extensive marble works in this city, who design working it immediately. It occurs in layers of varying length and thickness, and between each layer there is a stratum of clay. The colors are various, the principal being white, grayish white, and of a pink shade. When it is dressed the stone is translucent, and presents a beautiful appearance. The owners contemplate manufacturing this chalcedony into mantels and other house ornaments, as its use will give an elegant finish to a residence. The working of the quarries will afford employment to a large number of men and teams, as the rough stone will be hauled to San Luis Obispo for shipment.

A RICH DEPOSIT.—According to the Mining Index, the May Lundy mine, in Homer district, Mono county, is an immense mineral deposit and very rich. The croppings are hold bluffs of from 12 to 25 ft., and are rich in gold with some silver. Hundreds of tons of the ore on the surface will yield largely. At 254 ft. below the surface there are no indications of pinching or of a giving-out in richness. Twelve miners are now engaged in taking out and sacking the richest of the ore, which will work \$600 and upward to the ton, and the second-class ore, which will yield \$200, is stacked up for future use when the district is supplied with milling facilities, while the third-class—which, according to the Index, would be called high-grade ore in Bodie—is not taken out at all.

from the grain that the screen is capable of taking from it. The very great breadth of the screens (five ft.) and their rapid motion permits the grain to go through with great rapidity, notwithstanding the very thorough action of the screens. Sixty tons per day can be easily cleaned, so it is claimed, and the work is said to be perfect. From the above it will be seen that this cleaner is a very rapid and powerful machine, and is expected to do work that for speed and thoroughness has not hitherto been attempted.

MR. J. S. PHILLIPS, M. E., formerly of San Francisco, but now of No. 1 Wall street, New York, came to this city this week, en route to the Owens River valley, where he is to examine a mine for Eastern capitalists. The mine is the old Chrysopolis, about 10 miles above Independence, Inyo county. A 20-stamp mill was erected on this property some 15 years ago, but they failed, in some way, to treat the work successfully, and it has been idle ever since. Mr. Phillips will thoroughly examine the five or six veins of the mine, and will take a number of men with him to prospect the works clearly. If he condemns the mine, he will return in five or six weeks. If he approves, he will remain longer and start it swinging. Mr. Phillips has had many years practical experience in the mining business, and is the author of "The Explorers', Miners' and Metallurgists' Companion." The Eastern people have this time sent a man to examine for them who is practical in his views.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Mineral King District, Tulare County.

[Written for the Press by J. W. A. WRIGHT.]

The Empire mill started Wednesday last, as was proposed. Friday it made its first 24 hours' run this season and by 8 p. m. that day had crushed 60 tons of ore. Your correspondent is assured by good authority that nearly as much amalgam had been collected in these first three days as in its three weeks' run last November and December. The ore appears to be milling better than on its former trial, and parties most interested seem pleased with the result so far. But these results to date will be given at the close of this letter.

The Hallidie Wire Ropeway.

Or tramway, as it is here called, is working admirably, and greatly lessens the expense of delivering ore at the mill, and lumber with other supplies at the tunnel. As this is one of the most ingenious and interesting labor-saving inventions of our day, a brief description will be given for your readers who are not familiar with it.

Its main features are an endless wire-cable passing around two horizontal iron wheels with diameter of about 8 ft. one wheel at the mill, the other at the mine 2,000 ft. above it and over a mile distant. Every 200 ft. is a support or station made of four leaning supports of 10-inch timber 15 or 20 ft. high, or of the trunks of trees cut down to the proper height, where the tramway passes through the wood. On top of these supports is a strong horizontal beam, on each end of which is fastened a small grooved iron wheel over which the ascending and descending part of this wire belt passes. The cable used in this tramway is $\frac{3}{4}$ -inch in diameter and over two miles long. Attached to this cable at intervals of about 100 ft. for its entire length, are

107 Iron Buckets,

Each large enough to carry 100 lbs. of ore; also iron bars so crooked that 400 ft. of lumber of any length can be sent up or down in them; also a car in which two persons can be safely carried to or from the mine. The rods by which all these hang from the cable are so bent and attached to the cable that they easily pass over the supporting wheels.

The weight of the loaded cars (altogether about 5,000 lbs.) is the motive power that carries up the empty buckets, or lumber, or passengers. Each ore-bucket is rigged with a simple contrivance by which its bottom drops down and empties the load as it passes around the large horizontal wheel in the ore-house at the mill. Mr. Harper informs me that the ore is thus delivered from the mine at a

Cost of 20 Cents per Ton.

Breaks easily regulate or stop the motion of the wire.

The Standard mill at Bodie is furnished with a similar ropeway by Mr. Hallidie. To avoid the possibility of future injury from any winter's snow-slide, the new boarding-house for the miners, which must for convenience be near the mine, is being built of logs, is 20x100 ft., and is located on a ridge in the woods through which the tramway passes, at an altitude about 9,500 ft. Usually there will be but little danger from such avalanches as that last winter which destroyed the former lodging-house, for then a most uncommon amount of snow fell in the continuous storms of April. It fell on top of the winter snow, the surface of which was hard and ice-like, forming a good sliding surface; hence the deep accumulation of fresh snow was readily set in motion.

It is very wonderful that—though Mr. Fleming and 24 others were asleep in the two-story lodging-house when it was struck by the snow-slide April 19th last, torn in pieces, and its fragments scattered for 600 ft. below its site—not one of them was permanently injured. More remarkable still, though they were exposed bare-footed and not half clad for several hours, under and in the snow, before they were rescued early next morning, and though they suffered much in consequence, not one lost a toe or finger by frost-bite.

Getting the Hoisting Engine in the Cave

Of the Empire mine was no small feat of engineering skill. This was done in June while there was still considerable snow on the mountain sides. Mr. Harper informs me the hoiler weighed 2,100 lbs. It was dragged up on a sled by six yoke of oxen, attended by four men, a distance of fully two miles, and in places over an incline of 45°. This alone required two days. The hoisting reel, which weighs 1,800 lbs., was taken up in a similar way. Then there were 175 ft. of 14-inch smoke-stack to take up, that the smoke might be carried, as it is, 25 ft. above the entrance by passing through a natural shaft from the cave.

All this hoisting machinery was in place and ready for use in six days after it reached the tunnel, and in two weeks after it was brought to Mineral King Flat. Machinery could not work better than does all connected with mine and mill at present.

The force now employed in and about the mine numbers 35, and 25 more are soon to be added. There are 14 in the mill and assay department; so they will employ in all about 80 men. I should mention that the assay department is thoroughly equipped. The company

also own a large store well supplied. This is under the special charge of Col. C. B. Wagner, though Mr. Harper has general control of everything. Col. Wagner, who, with W. Davidson, Samuel Smith and two ladies, alone remained here the whole winter, informs me that

The Entire Snowfall

From October to April, inclusive, was 35 ft. Allowing, as usual, 10 inches of loose snow to 1 inch of rain, this would make 42 inches of rain for the past season. Mr. Stephen Barton, who has an interest in several ledges here, informs me that he measured about 22 inches for the season at his place on the Kaweah, 25 miles below here. At Pogue's ranch, where the Kaweah leaves the foothills, 20 miles east of Visalia, the season's rainfall was about 15 inches; at Visalia, 12.81 inches; and at Hanford, 20 miles farther, due west, 12.32 inches.

The coldest temperature here was 2° below zero one morning, and 4° below at another time. The general range of the mercury at 7 a. m. was from 16° to 20°. Some days it did not rise above 32°, though other days it was 90° in the sun. In the town of Mineral King snow stood at one time eight ft. deep. The first snow fell in October, but the ground was not covered constantly till the latter part of January. Bare ground first began to appear again by April 1st, and then the warm season was supposed to be opening. But soon the heavy snows began, lasting about three weeks. There was no bare ground in the "flat" again—altitude 7,500 ft.—till the latter part of May.

Another letter will tell your readers something of the magnificent scenery in this part of our "Higher Sierras."

The Cave in the Empire Mine

Deserves farther notice. Like several other smaller caves in the district, it exists in the great mass of limestone which, on Empire hill and neighboring heights, forms much of the "country rock" hereabouts. The main cave, in which the hoisting engine is placed, and from the floor of which the new winze has been sunk 102 ft., at an angle from 55° to 60°, according to the dip of the ore-stuff, is about 100 ft. long by 20 to 60 wide; while its rough gray roof overhead is from 30 to 100 ft. above you at different points. Before the walls and natural ceiling were made dingy by smoke, they were white and glistening; for the formation is really a coarse-grained white marble, as is shown by fracture. No stalactites or stalagmites appear, however, and this is to be accounted for, perhaps, by a remarkable absence of percolating water. The cave, and winze, and various drifts, and crosscuts, so far as developed, are very dry, so much so that water to run the hoisting engine is introduced through an iron pipe from a stream near the mouth of the tunnel. Not only do several small natural passages find their way upwards to the sloping mountain surface, but if you go 80 ft. into a 140-ft. drift running north, you come to a small and almost horizontal passage, which has been explored by Mr. S. Jewell, foreman of the mine, some 200 ft. by crawling. In this he found some water, and beyond the point he reached, he could hear water falling, and apparently to quite a depth. The irrepressible rat is found occasionally in this cave, the only animal form that finds its natural home in that lofty subterranean chasm.

But let us leave the cave, go to the mouth of the 350-ft. tunnel, enjoy a glance from our 10,000 ft. of elevation at the Tulare plains, their dark strips of timber, their yellow grain fields, the glimmering lake, the shadowy Coast Range mountains more than 100 miles to westward. Then we descend to

The Town of Mineral King.

Two thousand ft., and more, below the tunnel. This is quite a lively hurg for a mining district so little developed, as yet. It consists of two hotels, one boarding-house, one restaurant, two saloons, four stores, and about a dozen dwellings. The population of the district is not far from 200 at present. It is certainly a very quiet, orderly mining town. Before closing this letter, I have had a friendly chat with Mr. Harper, to learn what I may state of the prospect after five days' run of the mill. I am authorized to say that a clean-up will be made about Wednesday; that some bullion will certainly be obtained, not, however, so free from lead and iron as was hoped. Mr. Harper is now satisfied that more of the silver in their valuable ore can be saved by roasting before milling. He will recommend roasting works, which can be erected at an expense of about \$10,000, in a month or less.

Mineral King, Aug. 3d.

IMPORTANT AFRICAN EXPLORATION.—The irrepressible Stanley was on the Congo at last advices, with the view of opening to commerce the very heart of the African continent. His expedition is very strong, comprising 20 white men of different nationalities, and about 100 negroes of Zanzibar, Sierra Leone and the Congo. He has five small steamers and a number of smaller boats, with which he has taken his party and supplies up the river as far as the first of the series of 32 falls on the river. From this point the task of cutting a road through the wild coast range of mountains has been begun, when the boats and supplies will be transported overland past these obstructions to navigation, and then the great river and its tributaries will be navigable to the very heart of Africa. This expedition promises to be the most important undertaking in its practical results, that has ever been attempted in African exploration.

Summit Valley District, Montana.

[By J. E. CLAYTON in the *Mining Review*.]

Summit Valley mining district is situated in the southeastern portion of Deer Lodge county, in a large basin bounded on the east and west sides by high mountain ridges that trend nearly north and south, about 10 miles apart, and on the north and south by high lateral spurs and rolling hills that stretch across east and west from one range to the other, thus enclosing a beautiful mountain valley and basin of low, rolling hills, about 10 miles in diameter.

The Ores and Minerals.

The "gangue-stone" of all the lodes is quartz, more or less mixed with carbonate and silicate of manganese. Usually the quartz gangue largely predominates, but occasionally the manganese is found in greater quantity than the quartz. Above the water line the manganese is oxidized and black or brownish black in color; below water it has a beautiful pinkish and flesh tint. In most of the lodes are found places where the quartz and manganese gangue are mixed or blended with the feldspar-porphry above mentioned. In such cases a portion of the feldspar has been dissolved out and replaced by quartz and the sulphides of other metal such as iron, zinc, copper and lead, carrying silver and gold. Nearly all the gangue-stone below water is heavily charged with the above named sulphides in greatly varying proportions. Above water the sulphides have oxidized and partly leached out, leaving a cellular quartz more or less impoverished by the leaching process.

Native silver and gold are occasionally found in the surface ores, but below the permanent water line in all of the best mines of the district native silver is quite common, in the form of wire silver in the cavities and flake silver in the cleavage lines of the gangue-stone.

A large number of the principal lodes of the district contain free milling ore above the water line, which varies according to locality from 25 to 150 ft. deep, that may be crushed dry or wet, and amalgamated without preparatory roasting. The percentage of metal saved by this method varies from 60% to 80% of the assay values—probably an average saving of 75% of the gold and silver contained in the ore. There is also a large number of lodes in the district that cannot be worked by the free milling process, owing to the large amount of oxide of manganese present, which interferes in some way with the amalgamation of the silver and gold.

Below the water line all the ores of the district are refractory, and cannot be reduced without roasting with salt before amalgamation, hence are called "roasting" ores, in contradistinction to "free milling" ore. At the Alice mill the ore is crushed dry, then roasted with salt in a revolving Howell's furnace, after which it is amalgamated in pans in the usual way. This results in the extraction of 85% or 90% of the silver, and a somewhat smaller per cent. of the gold.

It is, therefore, advisable to erect dry crushing mills, with chloridizing roasting furnaces, at the outset, in order to work all classes of the silver ores contained in the district. Strictly speaking, there are no free milling ores in the district, except portions of the oxidized ore above the water line, as before stated.

Cost of Milling.

I have been able to get reliable information from the Alice, Lexington, Silver Bow and Dexter mills as to the cost of milling the ores by the three methods above named. The Alice mill (20 stamps) crushes dry, roasts the ore in Howell furnaces, and amalgamates in pans in the usual way, at a cost of from \$12 to \$14 per ton. The Silver Bow mill (20 stamps) crushes the ore dry, and amalgamates in pans, without roasting, at a cost ranging from \$8 to \$10 per ton. The Lexington mill (10 stamps) crushes wet, and amalgamates in pans, at a cost of about \$8 per ton. The Dexter mill (15 stamps) crushes the ore wet, and amalgamates in pans, as usual, at a cost of from \$7 to \$10 per ton. These facts show that free milling ore can be reduced in a large way at an average cost of about \$9 per ton, and the roasting ore at an average cost of \$12 per ton.

Cost of Extraction or Mining.

The average mining costs are more difficult to arrive at. The size of the lodes, hardness of the ore and country rock, and the quantity of water to be raised, etc., must be carefully calculated in each special case. In the average lodes, such as range from three to eight ft. between walls, where there is not more than one-fourth waste, \$5 per ton ought to pay all costs of mining, including dead work, timbering and superintendence. I think \$5 per ton is about a fair average estimate for the principal lodes of the district, where proper appliances are used under proper management.

Hauling from the mines to the mills in wagons cost from 75 cents to \$1 per ton, where the distance does not exceed two miles, thus making a total of \$15 per ton for mining, hauling and milling the free ores, and \$18 to \$20 per ton for the sulphureted ore that require roasting. This, I think, is about a fair average estimate of costs.

The workable ores of the district comprise all the ore that will pay the costs of mining, hauling and milling, and the percentage of loss in reduction. The free milling surface ores must therefore give an average assay value of \$20 per ton to pay expenses and losses, and the roasting or refractory ore must carry about \$25

per ton. All ores of a higher grade will therefore give a net profit.

It must be borne in mind that the above estimates are based upon what is being done now. When we get railroad transportation, larger reduction works, and more skill in reducing the ores of the district, the work can be done at less cost.

The quantity of workable ore in the district that will assay \$20 to the ton and upwards, is enormously large, enough, in my opinion, to employ 1,000 stamps for 20 years to come. The workable ore taken in general, may be said to range in assay value from \$20 to \$200 per ton. The larger figures are, of course, exceptional, but as we approach the lower sum the quantity becomes immense. Forty dollars will probably represent the value of nine-tenths of the workable ores of the district, but it is too early in its history to undertake any close estimate of either quantity or average values. With the present partial developments we know there is a great number of large, strong, true fissure lodes, carrying good pay—certainly more than I have ever seen in any district of the same area—say three miles square, and that in the few instances where they have been penetrated below the water line, the ores show a largely increased value.

For quantity of good workable ore, characteristics of permanence, good local facilities and fair average mountain climate, Summit Valley mining district bids fair to become one of the most productive and profitable mining centers in the United States.

The Old Ophir Dump.

Parties are engaged in drifting out the lower stratum of the waste dump of the old Ophir, says the *Territorial Enterprise*. They have made a large excavation on the west side of North A street, that reaches down to the original surface soil, and from thence are drifting out under the barren waste. The stratum that is being mined out was deposited in 1863, and is of a reddish-yellow color, while the barren waste of later date is of a blue shade. The ore taken out is said to average about \$40 per ton. It is being hauled to a mill on Six-Mile canyon for reduction. In taking out this old-time waste some lumps of fine sulphuret ore are occasionally met with, showing that miners in the early days were very careless, tumbling down and sending out with the waste not a little good ore. It is known that much good ore still remains in the sound ground, from the surface down to a depth of 200 or 300 ft., in the old Ophir, Mexican and California ground. It has been many years since any work has been done in any part of the old surface ground. Mexicans who worked in said mines in former times have long had an itching to get into them on almost any terms. They evidently know of excellent pickings that were left behind. When this first work was done Americans knew very little about silver ores. Many Mexicans were employed, and our people were guided by what they said in regard to following up ore seams and in the extraction of ore. These men probably left behind some fat spots, with a view of getting at them on their own hook at some future time. It would doubtless pay well to give these old upper levels a thorough overhauling. There is probably stowed away in them as waste much rock that would now pay well for working.

A PROJECTED TUNNEL.—The projected tunneling of Mont Blanc is engaging the serious attention of French engineers, and, contrary to common opinion, they characterize it as an easier undertaking than that of the Simplon route. The estimates of cost for executing such a work are, in the case of the Simplon, about \$27,000,000, and in that of Mont Blanc only \$15,000,000. Furthermore it is claimed that the Mont Blanc tunnel will make the journey from Paris to Genoa some 97 kilometers shorter, and from Paris to Milan 44 kilometers shorter than by the Simplon route. The location of the tunnel is a point which has given rise to various opinions, but that which meets with special favor from the advocates of the enterprise is from Chamounix to Courmayeur.

NEW EXPLORATION.—We learn from the *Enterprise* that work is about to be resumed at this mine—situated at the north end of the Comstock, beyond the Utah—with a full force of men. The company now have everything in shape for steady work and expect to thoroughly prospect their ground before making another halt. It is a wholly unexplored region. As prospecting has never been pushed far outside of the city to the northward, the Keystone shaft is a start toward the showing up of the unknown region in that direction.

PARTIES ARE NOW AT WORK upon the coal mines in the Cajon Pass, says the *San Bernardino Independent*. Those interested as owners have sold to the railroad company for a good round sum if they can show the bed to be four ft. in thickness. From what is stated, it will not be long before it will change ownership, as they have about that in sight.

"RICHER than ever" is the report from the Prospect Flat mine, El Dorado county. The ground now being worked is as rich as the famous Bald Mountain of Sierra county. It has long been the belief of competent judges that there is a large area of fine gravel in that portion of the old channel.

MECHANICAL PROGRESS.

About Pressed Glass.

One of the features in connection with the glass trade not generally known is that the first article of pressed glass made was manufactured in this country. The way in which this branch of the manufacture came to be discovered was rather peculiar. In fact it owed its origin to a Massachusetts carpenter. The discovery came about in this wise: A carpenter who lived in the town of Sandwich, Mass., wanted an article of glassware made for some purpose not known now, and went to Doming Jarvis, who had a glass factory in Sandwich in 1827, and asked him if he could make the article desired. Mr. Jarvis told him that he could not make it, as it would be impossible for the glass-blowers to make such an article. This did not satisfy the carpenter, who was of a mechanical turn of mind, and he wanted to know if a machine could not be made to press glass into any shape. This idea was scouted at first, but, upon second thought, Mr. Jarvis and the carpenter got together and fashioned a rude press, and made their first experiment. This machine was intended to make tumblers, and when the hot molten glass was poured into the mold, which was to determine whether glass could be pressed, the experiment was witnessed by many glass-makers of that time. They were nearly all of the opinion that the experiment would come to naught, and were greatly amazed when the result of the experiment demonstrated that it was possible to press glass. From that time the manufacture of articles of glass by the use of pressing machines gradually developed until to-day the bulk of the glass manufactured in this country is made with presses. The first tumbler manufactured in the rough improvised press alluded to above, remained in Mr. Deming's possession for many years, and then passed into the hands of John A. Dobson, a well-known glass dealer in Baltimore, and at the Centennial exhibition the tumbler was broken by Mr. John H. Hobbs, and the fragments are now on exhibition in Philadelphia. The pressed ware manufacturers in America lead the world to-day in that class of goods, while the French and Belgian manufacturers exceed in blown ware. Nineteenth of the glass beer mugs used in Germany to-day in the beer halls and gardens are made in this country. The glass presses have been applied to almost all departments of the manufacture, and every day brings forth some improvements, which are gradually raising pressed glass up to the highest standards.

BOILER COVERING.—A correspondent of the *American Machinist* describes a tin boiler covering which has been tried with good effect on marine boilers to lessen the loss of heat by radiation from the surface of the boiler. The tin is supported by bands made of $\frac{1}{2}$ -in. band iron. Ties riveted to these bands keep them far enough from the boiler to insure an air space of from two to four inches and are placed close enough together to keep the band in shape. The bands are placed in position and IX charcoal tin put on in strips 22 inches wide by long enough to go around the boiler outside the bands with two lugs or clips to screw them together with. The end of the heater has a cover like a mammoth teapot cover made in halves the rim of which is slipped over the first band and covered by the first section of tin. Where the mud ports come, a hole is cut in the tin and provided with a rim with a flange extending to the boiler. At the front the tin covering is closed in against the boiler. The air inclosed by the covering is kept sufficiently humid by "fizzing" to make it a poor conductor and the tin throws back a large part of the heat which is radiated from the boiler.

HARDENED PAPER.—It has recently been discovered that by submitting paper or paper pulp to the action of chloride of zinc, and afterward subjecting it to heavy pressure, a substance is produced resembling in its characteristics both wood and leather. The new substance is capable of a great variety of applications, and is getting to be extensively used in the arts. There are also several other methods by which paper is converted into a leather or parchment-like substance, the product varying in character according to the treatment. One curious and useful application of these processes is to form the paper into rolls or sheets suitable for packing, and then, when in the pasty state, sprinkle plumbago upon it, and by strong pressure thoroughly incorporate pulp and plumbago together. The resulting compounds are found to make a most excellent packing for steam engines and pumps. —*Northwestern Miller.*

LARGE FORGINGS.—A steel shaft forged by Krupp, at the Essen works, for the steamer *Harry Brown*, built at Pittsburgh, weighed 10 tons. Another shaft, forged with three cranks and coupling-flanges, exhibited in Mr. Krupp's group of forgings at the Philadelphia Centennial exhibition, weighed 13½ tons. This is, however, a small weight compared with that of many shafts made by the same firm for ocean steamers. The forging for the large Krupp gun exhibited at the Centennial was more than three times this weight. Probably the largest steel forging ever made was a shaft produced at Essen several years ago. This shaft was 30 inches in diameter and 70 ft. in length.

Selecting Tool-Steel.

Hardness, tenacity, facility for working under the hammer, and of receiving temper, are requisites of good tool-steel. The presence or absence of some of these qualities cannot be ascertained except by actual experiment; yet good judgment will enable a man to ascertain, with an approach to accuracy, the quality of steel without subjecting it to the action of fire and water and the hammer.

Pure iron contains no carbon; but tool-steel contains from 1% to 2%. So small is this amount, that it is not surprising that it requires judgment and experience to select steel in the bar. One of the tests is to apply a drop of nitric acid to the surface of a fresh fracture. It will leave a black stain on good steel, but not on iron or low steel. Another test is to observe the color and texture of a freshly-made fracture. This should present a fine grain, with a dull, silvery luster, and of uniform color. Poor steel may show a close grain, but it will be mottled in color.

But the only sure test is in working the steel. Draw the end of the bar, heated to cherry-red, under the hammer, to a fine point. If it will admit of being so pointed, that is a good indication. Plunge it into the hardening bath while hot; and, when chilled, give it a few gentle blows with the hammer. If it is tough and does not fly, but requires some hammering and bending back and forth to break it, that is another good indication. If the fracture shows a fine, even, lively grain, the test is complete, and the workman may be satisfied. One of the best tests is to make and temper a cold-chisel from the bar. If it stands well the chipping on a casting, the steel will make good turning tools. But, after all, the good judgment of the experienced forger is worth more than empirical tests. —*Manufacturer and Builder.*

CASTING GAS PIPES VERTICALLY.—The subject of casting gas pipes vertically in 12 ft. lengths bids fair to become one of considerable importance in the estimation alike of pipe foundries, gas managers, gas companies, etc. It seems that vertically-cast pipes of that length down to four inches in diameter are extensively produced in the U. S., whereas in Glasgow, which is the largest seat of the pipe founding industry in the world, it is seldom that such pipes are made of less than 15 inches in diameter. Two or three Glasgow firms are said to have tried to produce pipes of the kind referred to down to eight inches in diameter; but owing to the great difficulties connected with their foundry plant, waste, etc., the results have been anything but satisfactory. It is urged that Scotch pipe foundries should not hesitate to spend some effort in learning what improvements have been made in pipe-founding in America, so that 12-ft. lengths of piping have become a regular article of trade. Doubtless gas managers would welcome the advent of such pipes in this country, as their use would effect a great amount of economy in jointing, and therefore a large saving in leakage which has so widely and so frequently to be deplored. —*Journal of Gas Lighting.*

EFFECT OF HIGH SPEED OF ENGINES UPON CONDENSATION OF STEAM.—At the recent meeting of the Master Mechanics' Association, Mr. C. A. Smith, of St. Louis, reported the results of a series of experiments made to ascertain the temperature of steam cylinders during the working of the engine at varying speed. The experiments were made upon a locomotive hauling a light passenger train, the steam being throttled except at highest speed, and were continued through a run of 33 miles. It was found that, whereas when the engine was making about 50 revolutions per minute the instrument indicated a change of temperature of 120° during each stroke, at 100 revolutions per minute the variation dropped to 60°, at 200 revolutions to 30°, and 300 revolutions to 20°, the amount of variation being thus inversely proportional to the speed.

ELECTRICAL BOILER INDICATOR.—By means of an electrical indicator invented at Rouen, France, the water level in a steam boiler may be ascertained at any distance from the latter. The apparatus consists of an indicating tablet, which may be placed in any part of the establishment, connected with the electric indicator which is fixed at the top of a vertical tube above the boiler. Wires and platinum plates are so arranged that when the water in the boiler sinks to a certain point, an electric current is established which rings a signal, while at the same time the sign "low water" appears on the indicating tablet.

PROTECTING IRON FROM OXIDATION.—Mr. Bower's plan for protecting iron against oxidation by treating the cleansed surfaces in a chamber of suitable size with heated air, and subsequently reducing any red oxide that may have been formed by the introduction of reducing gases, is reported in London *Iron* to have been developed on the commercial scale very satisfactorily. It is said to have become a dangerous rival to the process of Barff, who employs superheated steam for the same purpose.

A STEAMER known as the *Anthracite* is on the way from Falmouth to New York. The voyage is for the purpose of testing a new system of tubular boilers. The boilers are charged with fresh, distilled water, which, after being condensed into steam once, may be re-condensed and re-used with very little loss in quantity.

SCIENTIFIC PROGRESS.

Progress in Chemical Discovery.

The progress of chemistry, when viewed from the position attained by advanced workers in the science, presents possibilities of discovery in the near future that are calculated to startle even philosophers of the *nil admirare* sort.

The most obvious manifestations of change that meets the student of twenty years ago, is the revolution that has taken place in the nomenclature of the science—a change that has completely robbed his acids, alkalis and salts of their old familiar aspects, and which perhaps more forcibly than anything else indicates how complete has been the change in chemical thought within this comparatively brief period. But however radical may have been the changes that have taken place in the views of chemists respecting the methods of indicating the molecular arrangement of chemical compounds, these innovations are trifling when compared with the views entertained by certain advanced thinkers respecting other questions of prime importance.

The stability of the elements themselves is now being questioned. Lockyer, not long ago, advanced the opinion, based upon spectroscopic evidence, that the so-called chemical elements were in reality not simple, but compound bodies; and hardly had the chemical world recovered sufficiently from the perplexity into which Lockyer's bold hypothesis had cast it, than the brothers Meyer announced its most startling verification in their remarkable experimental dissociation of chlorine and the other halogens. Changes of opinion no less radical have taken place likewise respecting the functions and properties of the different portions of the spectrum. It is now known that the whole of the spectrum acts actinically. Capt. Abney has demonstrated the fact most amply by preparing a form of silver bromide that is sensitive not only to the ultra-violet rays and the whole of the visible spectrum, but likewise to the infra-red, and has presented to the Chemical Society of London a magnificent map of the infra-red spectrum. How far these remarkable discoveries may pave the way to the realization of photographs in natural colors, or what surprises may be in store for us in the investigation of the infra-red absorption spectra of various substances, no one can venture to say.

We will now turn to another active field of discovery—that of organic chemistry—and progress no less remarkable confronts us. Following up the path opened by Hofmann, Perkins, Graebe and Lieberman, in producing the anilines and alizarin—the coloring principle of the madder root—other chemists no less diligent and far-sighted, are boldly attacking the problem of the constitution of other and even more complex substances, and it is by no means improbable that in the near future we may witness the artificial production of indigo and the organic alkaloids on a commercial scale. —*Manufacturer and Builder.*

EXPLOSION OF TOUGHENED GLASS.—A correspondent of the London *Nature* writes from Sonnighill, Eng., under date of July 7th, as follows: The night before last a lady of my family emptied a paper powder composed of seven and one-half grains of carbonate of potash and seven and one-half grains of carbonate of soda into a tumbler of what is called toughened glass less than half full of cold water. After stirring the mixture she drank the contents, leaving a silver teaspoon in the tumbler, and then placed the empty tumbler on the table by her side, within perhaps a foot of a burning duplex lamp. About five minutes afterwards a sharp explosion occurred, which startled all in the room. We found the tumbler shattered into fragments, the body of the glass ripped up, as it were, into several large, irregular-curved pieces, and the bottom of the tumbler broken into small pieces more resembling thick rough ice than anything else. Query: Was the explosion caused by the inherent properties of the toughened glass, or by the contact of potash, soda, the silver spoon and proximity to a lamp, the heat from which was very slight, indeed scarcely perceptible to the hand at the spot where the tumbler stood? The accident might have been very serious, for pieces of the glass flew to within a very few inches of the lady's face. A solution of the cause of the explosion is therefore of considerable importance to all who may have occasion to use vessels of this peculiar glass.

ARTIFICIAL CORUNDUM AND SPINEL.—M. Meunier has succeeded in making artificial corundum and spinel. The latter is made by heating together to redness, in a porcelain tube chloride of aluminum and magnesium and conducting steam over them. The tube will, after cooling, contain an apparently amorphous mass, which, however, is found under the microscope to consist of minute octahedrons. Gahnite is obtained by using zinc instead of magnesium. Corundum is produced in the same manner in which Gay Lussac obtained hematite or iron glance, by the decomposition of chloride by means of steam, and Daubree cassiterite with the aid of tin chloride. Meunier simply decomposes chloride of aluminum by means of steam, at a red heat, and obtains hexagonal plates of artificial corundum, the same substance as the sapphire, the ruby and the emery. —*Iron Age.*

ON THE DETERMINATION OF SULPHUR IN COAL. Nakamura, a student in the Engineering College at Tokio, has devised a new process of determining sulphur in a coal, which seems to work well. It consists in heating the coal below a red heat in contact with alkaline carbonates, by which the coal, whether bituminous or not, rapidly undergoes, without evolution of smoke, complete staphoric oxidation in a manner hardly to have been expected. On one part of coal, in very fine powder, take three or four parts of the mixed alkali carbonates. Mix intimately in a platinum dish, and heat at first gently, using alcohol in place of gas, to avoid the sulphur of the latter. Raise the heat very slowly, not reaching a visible red until the surface of the mass becomes faintly gray. Then heat to a faint red, and keep it there for an hour, when the mass will be nearly or quite white. It is then treated with water, filtered, and the sulphuric acid determined in the filtrate, as usual. The complete combustion of coal and coke at so low a temperature is noticeable. The carbonate seems to exert no chemical action in the case, but acts mechanically, apparently the spaces between the particles allowing a draft of air, and the combustion proceeding from the bottom toward the top. Direct experiment shows no loss of sulphur, and comparative tests prove the results to be accurate. The complete roasting process occupies about an hour and a half. —*Jour. Chemical Society.*

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 29th annual meeting for this year in Boston, commencing on Wednesday, August 25th. It is expected that this will be the largest and most important meeting of this body hitherto held. Persons desirous of becoming members and taking part in its exercises, with all the privileges of membership, can do so by forwarding the fee of \$8, in advance, to the Secretary of the Association. To all such members tickets will be sent. Any person may become a member of the Association upon recommendation in writing by two members or fellows, nomination by the Standing Committee, and election by a majority of the members and fellows present in general session. Blank forms for recommendation to membership will be furnished on application by letter or otherwise to the permanent Secretary, F. W. Putnam, Esq., Boston.

ARTIFICIAL QUARTZ.—Many different methods have been used for the artificial production of quartz. Crystals were made by Senarmont by heating gelatinous silica with hydrochloric acid; by Danbree, by means of the action of superheated water upon glass; by Hantefenille, by treating silica at a temperature of 750 to 800° C. with sulphate of soda. Friedel and Sarasin have recently employed a different method. They placed in a closed steel tube lined with copper a mixture of potash, alumina and an excess of amorphous silica, water being present. After exposing the tube to a dark red heat for periods varying from 14 to 38 hours, they found that almost the entire quantity of silica was crystallized, small, quite fully developed individual crystals being obtained also.

REDUCING POWER OF GRAPE-SUGAR.—Prof. Botger highly recommends the use of glucose in alkaline solution for the reduction of salts of silver, affirming that there is no procedure that is so convenient or which gives surer results. He proceeds in the following manner: Chloride of silver freshly precipitated and well washed, is suspended in a suitable quantity of a diluted solution of caustic soda. To this a small quantity of glucose is added, when, on boiling for a few minutes, a complete reduction takes place. The metal, if collected, washed, and slightly calcined, may be obtained in form of a spongy mass of dull white color. The same method yields a very active platinum black.

MAN ON THE AMERICAN CONTINENT.—In a recent lecture by Prof. Flower, before the Royal College of Surgeons in London, the question of the origin of man on the American continent was discussed at some length. The statement was made that, "taking all circumstances into consideration, it is quite as likely that Asiatic man may have been derived from America as the reverse; or both may have had their source in a common center, in some region of the earth now covered by the sea."

A NEW PHENOMENON OF MAGNETISM.—It is well known that the ratio between the residual and the temporary magnetism of a bar of steel enveloped by a magnetizing coil, diminishes as the bar becomes shorter and thicker. M. Aug. Kighi was led by theoretical considerations to a conclusion which is opposed to ordinary phenomena, but which experience has confirmed in every particular. It is this: If we take bare of the same steel and of the same diameter, but of diminishing lengths, we finally reach a length which shows no magnetization, and with still smaller lengths we obtain a residual magnetism which is opposite to that of the coil.

IRON AND HYDROGEN.—At a late meeting of the English Institution of Mechanical Engineers, according to a correspondent of *Nature*, Prof. Hughes stated, in relation to the occlusion of hydrogen in steel and its influence in hardening, that the experiments which he had made did not support the ordinarily-accepted hydrogen theory; but rather the view that *hardened steel* was an actual alloy of carbon and iron, while *unhardened steel* was simply a mechanical mixture. Experiments are now in progress, designed to test the truth of this view.

The manufacture of paper bricks is said to be carried on extensively in the West. The quality of the bricks render them well adapted for building purposes.

MEETINGS TO BE HELD.

NAME OF COMPANY.	LOCATION.	SECRETARY.
------------------	-----------	------------

laps the Rex Monti series, and the other rich mines on the north side of Kearsarge mountain, will prove one of the most important mining works in the State.

KEARSARGE TUNNEL.—Supt. Gray has again resumed work, with a small force, in this tunnel. He is running on ledge matter, occasionally striking small spots of the rich blue sulphate ore, which was found in the lower level of the old workings.

MONO.

BODIE DISTRICT.—*Free Press*, Aug. 3: Supt. Taylor's letter of this date shows that the Noonday ledge looks well and is yielding good ore. The pair of new boilers at the boiling works are up and everything connected with them will soon be completed. The additional building at the Noonday mill for 10 more stamps, is well under way of construction.

HOMER CO.—The south drift on the Wasatch ledge shows continuous improvement as to size and quality of ore. The ledge is from 35 to 6 ft in width; samples of quartz assaying in gold give \$2,310.00; silver, \$91.25; total, \$2,401.25.

STANDARD CO.—There is the usual amount of work going on in all parts of the mine. All the ledges on the various levels look good and yield the same uniform good character of ore that has been taken out for some time past. In the north stopes, 350 level, the ledge continues about 20 ft wide, and in the south end the ledge is 7 ft wide.

MCLINTOCK.—The new shaft is now down 502 ft. It will be continued right along, but at the 600 level a station will be cut out and developments continued. The bottom of the new shaft at this station will be about 125 feet from the bottom of the incline, and where there is an 8-ft ledge of ore assaying from \$15 to \$30.

BEVERLY.—The work of handling ore to the Syndicate mill was begun yesterday. It is intended to commence crushing as soon as cleaned up of Standard ore. Forty tons of ore per day are required to keep the mill going regularly, which it is expected to do for some months to come. Much of it is very rich and should altogether add materially to the output of the district.

JUPITER.—For some time past it has been known that a new and interesting discovery had been made on the 500 level south of the Jupiter mines. Early yesterday morning the ledge was reached and found to be stronger and richer than in its original discovery. The ore is rich in both gold and silver, the latter showing both free and leaf-like, as well as in the best form of black sulphates. It also possesses the stain of ruby silver ores, heretofore quite unusual so far north in the district, where almost wholly gold ore has been the rule.

BULLWER CO.—The company extracted and shipped 391 tons of ore to the mill last week from the 200, 250 and 350 levels. In the assays of the pulp average \$14.

GOODSHAW.—An upraise has been made on No. 3 vein of 15 ft. Some very rich ore has been encountered, showing assays averaging \$212.18 from rock taken from all parts of the ledge.

SOUTH BULLWER.—The ledge in the bottom has increased to 6 ft in width, and shows a marked improvement in its value of good milling ore.

NEVADA.

OLD GOLD TUNNEL.—*Nevada City Herald*, July 31: Parties who have been working for some time past on the old tunnel, situated a short distance west of town, have taken out a very good looking rock, which they will soon have crushed. The above-named claim has been worked on and off for quite a number of years, and has at times yielded some very rich paying quartz.

CUMBER.—The recent strike at the above-named mine proves to be very rich, and the ledge from whence the rich quartz is being taken is doubtless the Champion ledge of Cumber. The ledge is from 4 to 6 ft in thickness, and has been crushed, 33 of which yielded \$40 per ton, and 5 tons of assayed rock gave \$140 per ton. The entire crushing of 38 tons yielded 4 tons of sulphurates, which assayed from \$133 to \$140 per ton. The vein, which is 1 ft in thickness, has just been opened. A tunnel was driven nearly 50 ft before the ledge was struck, and is now in about 30 ft on the same.

WATKINS.—*Transcript*, Aug. 7: On Saturday last a ledge was struck on the 300 level, in the north drift of the El Capitán, which prospects very favorably. The ledge is said to be 14 inches thick, and looking well in sulphurates. The specimens exhibited were very favorable to the mine.

THE MORMON CO.—This company has commenced hauling the first 100 tons of ore from the Mohican ledge to the Pittsburgh mill.

INDEPENDENT.—This mine, which, for several months, had not been paying as well as formerly, as was indicated by decreased monthly dividends, has evidently recovered its position. The dividend for the month of July was \$5, and there are indications that the property will continue equally profitable for some time to come, as the ore deposits are steadily improving.

IRON GOLD QUARTZ.—Yesterday a stranger entered our office and showed a chunk of quartz of about 4 lbs in weight that looked as though 1 lb of fine gold had been shot from a cannon and imbedded itself all over the rock. After admiring it for some time we asked where the specimen came from. "I expected that would be your first question," said the stranger, "but as the ledge is a new location, and has not yet been recorded, I shall have to dole out giving on the exact locality at present, but in a short time I will give you full particulars."

OLD TUNNEL MINE.—The crushing of 11 tons of ore from the Gold Tunnel mine, made by Berry & Eddy, realized them \$15 a ton besides sulphurates, which are worth about \$40 more. The boys feel good over their success, and have gone to work taking out another crushing.

ALBERT GRAVEL MINE.—The first clean-up from this mine, situated on Selby flat, miles from this city, was made on Thursday, and from 30 carloads of gravel the owners realized over \$150. This they consider very flattering results, as they have not yet reached the best pay gravel.

SAILOR FLAT GRAVEL CO.—This company has, during the last month, been on short allowance of water, and has not been able to run more than 10 days during that time. They are promised 1,000 inches of water from the South Yuba ditch, either to-day or to-morrow, and then the dissolving of the high gravel banks in their claim will be renewed.

BLUE TENT CO.—North Bloomfield *Cor. Herald*, Aug. 3: The Blue Tent company's mine is running full blast. They have water enough to keep washing until rain falls again, and the general appearance of the mine was never better than at present. Twenty-five hundred inches of water are used in hydraulicking, 3 monitors being kept busy. The company is engaged in running a bedrock tunnel from the South Yuba river, which, when completed, will be in the neighborhood of 1,000 ft long; 500 ft have already been completed.

FORD & McDONALD MINE.—*Grass Valley Union*, Aug. 4: A shaft up 11 ft made of rock on the Ford & McDonald claim, on New York hill, has just been made, and yielded a yield of \$220 per load. Besides this crushing there had been selected from the rock a lot of very rich specimens.

PIETY HILL.—Mr. Fred Brown, who resides on Piety hill, has discovered a ledge in that neighborhood which promises well for the future. The rock prospects good, and a crushing of 10 tons, which has been taken out, will be made shortly.

MOUNT AUBURN MINE.—The reported strike in this mine is fully sustained by parties who have visited it the past day or two. The ledge was small when first discovered, but rapidly widened out until 4 ft thick. The rock shows well, and at this time it gives every indication of continuing to be a rich paying chute of ore.

PLACER.

RICH GRAVEL.—*Auburn Herald*, Aug. 7: We understand that the McCulliverty has struck some very rich gravel in the Dardanelles claim, near Forest hill, and at the close of the water season, which will be very soon, contemplates drifting. Once thoroughly opened up, there are undoubtedly some very rich gravel channels in the Forest Hill ridge.

MICHIGAN BLUFF NOTES.—The old Weske mine is again in operation under the supervision of Wm. Muir. He has about 15 men at work, with good prospects of success. He

is working the mine on a new plan which, it is hoped, will be profitable. The Breese & Wheeler mine is shut down for the purpose of repairing the mill and machinery. The El Dorado mine, at Last Chance, owned by Ray & Highland, is paying very large dividends.

NOTES.—*Dutch Flat Forum*, Aug. 7: We are happy to announce that the construction of a trail to the camps situated on Euchebe bar and Humming canyon is an assured fact, which, at no distant day, will be the great centers of quartz mining in Placer county; and, with easy access to them by roads and trails, these places will rapidly grow into notice and prominence, for the quartz there is very rich. Dutch Flat will be correspondingly benefited.

FRANKLIN MINE.—The Franklin mine continues to prospect well, as does the Shady Glenn. Should these mines meet the expectations of their owners, Dutch Flat will move forward as she perhaps never moved before.

PLUMAS.

BELL MINE.—*Quincy National*, Aug. 7: Work at this mine progresses steadily and satisfactorily, and the mill is running with good results. The rock in the lower level still continues to be very rich, and is being crushed satisfactorily. The rock from the upper stopes is also showing a little better all the time. The mill is paying at the rate of about \$100 per day.

JACKSON MINE.—The same company is sinking a shaft on the Jackson ledge, and is developing a large vein of pay rock. The shaft is 533 ft, and all in quartz, which prospects well and regularly. It is inclined to think that this will prove the best mine in that section when fairly opened. It is large and a perfect vein, prospecting uniformly, and although not wonderfully rich, yet there is plenty of gold to make it good pay, and it is so situated that it can be tapped, by tunnel, at an enormous depth. A run of the Bell mill will be made on Jackson rock before long.

MORRIS QUARTZ STRIKE.—The Susanville parties who came up from Granite basin on Monday, report that Mr. James See made a very important discovery a day or two before, in the shape of a quartz ledge which was literally tilted with gold. We did not learn whether the strike was in the Serrin claim, on which Mr. See has been operating, or something new; but in either case it is important. The quartz is said to be wonderfully rich, and the deposit bids fair to be very valuable. We are glad to hear of Jim's good fortune, as he has been putting in some "hard licks" in that section, and ought to prosper.

NOTE.—Mr. Williams, of Susanville, will soon erect a quartz mill for his own and for custom work, and the chance to have ore crushed, on reasonable terms, will stimulate mine owners there to develop their ledges.

SHASTA.

IRON MOUNTAIN.—*Redding Independent*, Aug. 5: It is reported that Capt. Blaisdell, of San Francisco, has bonded a claim on Iron Mountain (\$75,000) for 60 days, and that he is now on his way to New York on business connected with the Iron Mountain tunnel being run at the mine, and a fine body of ore reported. It is hoped that some action will soon be taken to prove up the value of this reported great discovery.

NOTES.—The Washington company is pounding away on 200 tons of rock, and it will be some time before the grand scrape-up is made. Steve Baker made a short clean-up of this—crushed 1 lb of quartz and got 15 cents out of it. Willey crushed 33 lbs and obtained \$7.57.

SIERRA.

THE 1001 MINE.—*Downville Messenger*, Aug. 7: The owners are still busy opening breasts, and they find better gravel than they expected. The company has a splendid mine, which is certain to contain an immense amount of pay gravel, judging from developments thus far made.

WOLF CREEK.—The Wolf Creek quartz mine has been bonded for 4 months to Dr. Manson, who is already at work developing the same.

AMERICAN HILL.—Wm. Jess is working on a large ledge near the old Von Humholdt, at American hill. The rock shows gold, calena and sulphurates of iron.

NOTE.—The owner of the above mine, who paid well this year, and the owner, who is in Scotland, will receive a dividend of many thousand dollars. John Kendall & Co. are at work opening a claim in the river just below the toll bridge. The water in the river is still very high, but in getting in no difficulty is anticipated. The American Hill company cleaned up last week. The company was unable to clean all their bedrock on account of a slide. We learn that the restaurant, the restaurant, the restaurant has leased the North Fork quartz ledge, and will proceed to prospect it immediately. Some of the rock taken out when the ledge was first discovered was remarkably rich.

TRINITY.

TAYLOR FLAT MINE.—*Weaverville Journal*, Aug. 7: The Superintendent informs us that a recent partial clean-up in the Taylor Flat mine afforded the most satisfactory results, and the ground now being worked give every indication of good pay. As they run back into the flat, the prospects increase and Mr. Walker is confident that the mine has one of the very best mines on the coast. Water holds out well, and it is thought the supply will keep up through the season.

TULARE.

EMPIRE MINE.—*Visalia Times*, Aug. 7: On Thursday evening, Mr. Thomas Fowler brought into town, from the Empire mine, the result of the first working of ore from the Empire mine. The ore is a silver-bearing quartz, weighing 105 lbs. The ore worked came from the 100 level. The strike of rich ore and the production of the silver brick produced an old-fashioned excitement in Visalia.

TUOLUMNE.

TWOA MINES.—*Sonoma Independent*, Aug. 7: These mines are continued to assume that important position claimed for them by the parties who have prospecting in that district. They are down only 5 ft to the Reindoller, and it is asserted by good judges that the prospect for another Comstock is very flattering. The miners and prospectors have established pack-train communication to Crano's flat, where they connect with the main Yosemite Road. Such parties have under consideration a road from the Crano's flat across the divide of 100 ft, which would be in the neighborhood of 30 miles.

NOTES.—The buyers of gold dust in Sonoma report a marked increase of their purchases this year over any previous year since 1870. An air-compressor will be put into the Keltz mine to drive a diamond drill.

NEVADA.

WASHOE DISTRICT.

SASOUE.—Following are the latest official statements to Aug. 10: The raise from the north drift, 1300 level, has been extended a distance of 27 ft. The first 20 ft passed through heavy clay, mixed with quartz and porphyry. For the first 10 ft the rock was very hard, and the same material now in the face of the upraise. On the 5th we completed the 2200 level hulkhead, and stopped the main pump this morning.

OVERMAN.—Incline upraise has been extended 30 ft without meeting any change of ground. Have started a vertical drift hole in zinc to see if we can sink to the 2300 level without striking too much water. This hole is now 75 ft in depth.

CON. IMPERIAL.—The west crosscut south of the south winze, 2500 level, is in 70 ft. We have stopped this crosscut and started one west 100 ft north of the south winze, which has been extended 17 ft. The face of this crosscut is showing a good deal of quartz.

CALADORA.—Diamond drill hole has been extended 50 ft through very hard porphyry; and, having struck a very strong flow of water, we have stopped drilling and plugged the hole.

BEUCHER.—During the week we have cleared up the sump and put up a new donkey pump. We have also cleared out and repaired track, etc., of the 3000 main south drift, preparatory to resuming work in the face. Work on the dump of this drift will be resumed to-morrow.

EXHIBITION.—The diamond drill is in 96 ft. In a northerly westerly direction from the main drift, 2300 level, The formation passed through is quartz and porphyry.

CHERRY CREEK DISTRICT.

TRACUP.—*Cor. White Pine News*, Aug. 1: This mine is opened by an incline to a depth of 770 ft, and shows a continuous vein of fine milling ore of the best grade. It has already produced \$500,000 and has more in sight.

GENEVA.—The Geneva mine has not been opened to any great depth, but sufficient work has been done to demonstrate the fact that they have a strong vein of fair grade ore, and with the expenditure of a small amount of money the Geneva is liable to prove a very valuable piece of property.

NOTES.—Work was commenced on the Box mine last week. The mine is situated on the upper belt, between the Teacup and Chance mines. The Box mine is also on the upper belt and joins the Teacup on the north. Its prospects are first class. Everything is running smoothly at the Star mill and mine. The bullion shipment for the week ending July 23th, was 10 bars, valued at \$8,300.

COLUMBUS DISTRICT.

NORTHERN BRILE.—*True Future*, Aug. 7: The crosscut between the 2d and 3d levels looks very promising, and from it considerable ore of good quality is being taken out. The 6th level is yielding as usual. In the level above the 6th the ore stopes are looking well and promise richly for the future. All work has progressed well during the week, both at the mills and mine. The aggregate output of ore is 104 tons per day.

MOUNT POTOM.—The extraction of ore has been resumed and additional men put on. There are 300 tons of ore at Belleville awaiting milling facilities, and there are also 175 tons in the dump awaiting transportation. The average milling assay of the ore is \$75. The mill at Belleville will be started shortly.

MOUNT DIABLO.—The winze below the 1st level is down 89 ft, and is in high ore. A drift has been started southeast from the drift on the 1st level to connect with the west drift from the bottom of the 1st incline from the old tunnel. This drift is now in 11 ft. The stopes and drifts in ore on the 1st level are looking and producing well.

WATSON.—The prospects of the Watson mine, the sinking of the shaft 9 ft. The total depth of this shaft is now 113 ft. The ore is looking very well.

LUCKY HILL.—Grading for the road to the mine is nearly completed, and the foundation for the hoisting machinery is nearly ready to receive the material.

TINKER.—Work is still progressing on this mine. The ore is looking well, and fair progress is being made.

KEYSTONE.—The prospect of the Keystone mine has been made this week on the crosscut running south.

EUREKA DISTRICT.

EMMA MINE.—*Seaford*, July 31: The owners of the Emma mine have sunk the incline 70 ft, and have uncovered a body of very good ore. They are driving work ahead as rapidly as possible. The ledge is 3 ft wide. Ore assays run as high as \$400. They have an excellent hanging quartzite footwall.

INDUSTRI.—The main shaft of this mine is down 52 ft. A drift has been run from the bottom of the shaft a distance of 95 ft, and is in low-grade ore. They have 22 tons of ore on the dump, and are about to break in the mine.

ORIGINAL BATTLE.—The owners are working vigorously, and expect to strike the ledge of rich ore that was reported some time since. They have found some small stringers of it, and a small cave was discovered.

EL DORADO.—The main tunnel is in a distance of 250 ft, and they are finding some pockets of rich ore, the assays of which average from \$300 to \$400. A drift has been started in a northward direction, and it is expected that in a few days it will open into a body of ore. About 20 tons of high-grade ore are on the dump ready for shipment.

PARADISE DISTRICT.

BULLION MINE.—*Silver State*, Aug. 4: It is impossible at present to give a definite estimate of the extent of the recent strike in the north drift of the Bullion mine. The ore, however, is exceedingly rich in both native and ruby silver, but it will be several weeks before even a comparative estimate can be given of the extent of the ore body. The deposit was encountered in the upper drift, and a drift is being run to strike it on the winze ledge, and if it extends even to that depth the strike may be regarded as the turning point in the history of the company.

NOTES.—We have learned these particulars of the results of the working of the second-grade ore from the Ohio mine, at the Bullion company's mill: The battery samples assayed \$95 to the ton, and the ore worked up to 33 1/2 of that assay by the ordinary wet process.

PHILADELPHIA DISTRICT.

BELEMONT.—*Cor. Courier*, July 31: The mine is steadily improving, as the stopes are extended north and south from the Hogan upraise, showing a continuous vein of good ore. Have driven the stopes north 35 ft, south 15 ft, and are still continuing north and south in end of stopes. Will take out about 10 tons of first-class ore this week and 20 tons of second class.

BARCELONA.—Have been detained 2 days from north level securing up and making necessary improvements. This level continues to look well; ledge well defined and both walls perfect. I will start the Ingersoll drill next week to push north level ahead as rapidly as possible, as it promises a large quantity of high-grade ore.

WHITE PINE DISTRICT.

EBENHART MILL.—*News*, Aug. 7: This mill is of late turning out large quantities of analcam. It is now running to better advantage than at any time since the work of running the tailings was commenced.

SILVER CANYON ITEM.—Perly Rowell, who has the contract for putting up Dr. Brooks' 10-stamp mill at Silver Canyon, left for that place yesterday morning, in company with John McLean, by private conveyance. Work will be commenced at once, and Mr. Rowell expects to have the mill ready to start up by the middle of October at the furthest.

ARIZONA.

YAVAPAI COUNTY.—*Arizona Miner*, July 30: As work progresses in the Silver Prince its marvelous deposit of silver ore becomes richer. A depth of 130 ft. Now at 72 ft deeper a foot of solid ore, assaying over \$2,000 to the ton, is found, while 2 or 3 ft of other metalliferous quartz exists, which assays over \$200 to the ton.

GRON CREEK.—From mining gentlemen from the East who are visiting this section, we are informed that they pronounce Gron Creek district as one of wonderful richness and magnitude unequalled anywhere.

NOTE.—The Golden Era M. Co. think of removing its mill from Cherry creek to the heart of innumerable mines around Gron creek. With improved machinery added to the mill for the proper working of the rich ores of the district, good results must follow to the owners of the mill, as also the owners of the cor.

PRIMA COUNTY.—*Cor. News*, Aug. 7: The prospect of the Prima mine has been made in the Whetstone mountains within a few days. It assays up in the hundreds at a depth of 13 ft.

NOTES.—For a few days the Contention mill has been idle for want of ore, not having had a surplus on hand when the rains commenced. The large ore teams "stuck," but all is right again and the batteries are thumping and pounding away as usual. Prospectors are preparing to take to the mountains. The prospects for water and grass are excellent, and the demand about here for horses, mules and jacks has cleaned out the market. The contractors, Maltor & Lind, have finished the grading for the Sunset mill and, as soon as lumber arrives, commence erecting the mill.

PRIMA COUNTY.—*Silver Bell*, July 31: The upraise in the Ireno is being pushed as rapidly as possible, the entire face still in good shape. The connection will soon be made with the shaft and this will give good ventilation and make room for a large force of miners, which will be put on as soon as convenient. Work will be resumed on the mill, and when finished there will be an abundance of ore on the dump for reduction, thereby greatly adding to the bullion shipments.

TOWNSHIP.—Development on this mine is progressing very favorably. The ore body in the upper drift (to the

southwest) shows a width of 6 ft, and in the lowest shows an increase width of 15 inches. In the last 10 days the upper drift is now 130 ft in length, and the lower 120, and a continuous ore body the entire length of each.

NOTES.—The Silver gulch ore is reported as showing better, and more of it, than heretofore. Our last report stated it as high grade. Some of the ore has been taken to the Mexican mill for reduction. The Cox & Coplin, in the drift, 100 ft from surface, is opening rich, having revealed black sulphides, some of the best of which has assayed \$30,000. Work has been commenced on the Los Angeles group of mines. Hayse & Buck's mine is, indeed, turning out extraordinarily rich ore.

NEW DISTRICT.—We learn from A. C. Webster, who has returned to Globe from a prospecting tour, that he has made valuable locations in an unnamed district. The Sample and Silver Queen claims he regarded as the most noted in that locality. The Sample has a 12x12 foot shaft, 60 ft deep. On the Sample dump there is between 200 and 300 tons of milling ore. The Silver Queen has a 70 ft shaft, 5x7 ft. In this shaft is shown a 2 1/2 ft vein of \$50 free milling ore. The camp has been hastily prospected and many locations made.

COLORADO.

CENTRAL COUNTY.—*Silver Cliff Prospect*, July 31: We were shown a fine specimen of galena taken from the Dora mine near Dora, at a depth of something over 50 ft. It was struck yesterday and looks to be quite rich in silver, and extends over the entire bottom of the shaft without any well rock being struck. The property belongs to the Leavenworth M. Co., and promises fairly by sufficient development to become a very valuable mine.

NOTE.—Parties from the newly discovered Kirby district report many fine prospects in the vicinity. We have over there they located the Fairplay, Criticism, and Emmit claims, carrying galena and chlorides running from 87 to 244 ounces.

CONJOS COUNTY.—*Cor. San Juan Prospector* July 31: The camp of Cornwall is located on the Alamosa creek, 8 miles east of the Summit mining camp, and 17 miles almost due south of Del Norte, in a park 1 mile wide by 1/2 mile long, known as Elk park. The area of the mining locality is, so far as reported, about 10 miles square. The ore of the camp is chlorides and black sulphurates. Prof. Cherry and others say that the ores are free milling—can be reduced for from \$4 to \$5 per ton. The country rock is trachyte. The ore is quite soft and can be easily mined. It is claimed that the veins, in general, are true fissures.

PARK COUNTY.—*Fairplay Plume*, July 29: We are again able to note a good strike on the Mudmill property. For some days it has been improving right along, and since Monday the miners have been taking out a true carbonate ore and sulphurated sand, that encourages the belief that the Mudmill is to become a very valuable property. The lowest assays recently run from 40 to 130 ounces.

NOTE.—The Sacramento company continues to put out the usual amount of ore. The product of this mine alone for but 6 months past has been equal to one-fourth of what the entire mineral product of the county was in 1879. On the Sherwood mine a good thing is said to have been struck. The Sherwood is on the Little Sacramento break-off, not far from the Emma mine. Within a week the owner has opened a body of galena ore which he thinks will run high in silver. A small force of men resumed work on the Crappo mine the first of the week. The owners of this property are getting in shape for some big operations.

IDAHO.

BAY HORSE DISTRICT.—*Idaho World*, Aug. 3: From Harry Lester, who has just returned from Bay Horse district, we gather the following notes: More men are at work in Bay Horse district than in the Yankee Fork country. Two smelting furnaces will be erected in Bay Horse the coming fall. The road was completed from Challis to Bay Horse creek when Mr. Lester left, and they were about ready to take in one of the furnaces, which has been lying at the former place for some time. The other one, which was put up on Kinnickinick, has not yet arrived, but is expected before long.

WOOD RIVER.—We are informed by Mr. Hoskins, who has just returned from the Wood River country, that the mines in that country cannot be surpassed for surface prospects. Whether or not the mines are permanent is yet to be determined, as no great depth has been attained on any of them. Twelve or 15 miles of mines have been made thus far.

YANKEE FORK NOTES.—*Herald*, Aug. 3: The ore sacked for shipment in the Badger mine the past winter is worth from \$700 to \$800 per ton. It will probably go out to the Bay Horse reduction works for treatment. The mine is looking well, and the Badger can be set down as one of the numerous profitable veins of the district. J. O. Fox has commenced sawing and delivering 50,000 ft of lumber to the Cor. Yankee Fork gravel mining company. Grading for the Custer mill-site and work on the two-story office building, is progressing rapidly. Chris. Moler's arastra is running on Badger ore. The mines in this district continue to improve as they are developed.

MONTANA.

DEER LODGE COUNTY.—*Butte Miner*, Aug. 3: The fine show in the Anselmo mine when the drifts were first started east and west at a depth of 75 ft, it has continued to steadily improve from that time, and for the amount of work done has no superior in the camp either in richness of the ores or in indications of permanence. The west drift is now in 60 ft. In the face is a 2-ft body of high-grade ore, the ledge dipping to the south. Only the foot wall is yet visible, but this is smooth and well defined. Recent assays of the ore show it to contain from 250 to 500 ounces, and a 50-ton lot has recently been shipped to the smelter.

STAR WEST.—The main shaft at noon yesterday was down 104 ft, the ore in the bottom remaining about 3 ft wide and showing no change in character or richness. The various stopes and drifts are all in ore, and producing satisfactorily. The shaft near the extreme west end of the claim is now being worked, though the bottom is about 40 ft from the surface, will be extracted as fast as required. The new shaft is 30 ft deep.

GRKY ROCK.—Stopping is actively progressing in the east and west drifts, and a body of ore averaging 10 ft in width, running along the entire length of the level and up to within 40 ft from the surface, will be extracted as fast as required. The new shaft is 30 ft deep.

NEW MEXICO.

SANTA FE.—*Grant County Herald*, July 24: Mining matters in Santa Fe's vicinity are lively. Bonanza City, Carbonateville, Poverty Hollow, Hungry Gulch, Silver Buttes and the Old and New Placers are healthy camps. The vigor, and are now beginning to give some returns for labor and money invested. The camps contain about 800 men. The New York & New Mexico mining company's smelter, of 30 tons capacity, will be in operation in a week, employing already 50 men.

SILVER CITY NOTES.—The Providencia mine, on Chloide flat, is looking first-rate, and the ore taken from it is as good as that from any mine in the district. The main shaft is down 150 ft, another 130 ft, and several others to a lesser depth—all showing good ore.

THE 76 MINE.—There has recently been discovered in one of the crosscuts of this mine a large body of silver-bearing slate, which has caused some of our mining experts a good deal of brown study. Where the tunnel was cut through this slate, in its exposure, it was found to be 24 ft, horn silver is found all through the slate, and in the seams broad sheets of native silver, no thicker than tissue paper, are found.

A MEMORIAL WINDOW, to which Americans have contributed largely, will soon be placed in Canon Farrar's church—St. Margaret's, Westminster, London—in memory of Sir Walter Raleigh.

The Comstock North End.

But little remains to be added to what has been said of operation in the Union, remarks the *Gold Hill News* of the 5th inst. The Union shaft has been connected with the 2500 station of the Sierra Nevada incline. This connection has been made through 30 to 35 ft. of quartz including 20 feet of good milling ore. It is doubtless the heel of the ore body on the 2500 level of Union. The toe is not yet uncovered.

As was said in yesterday's issue, the Union shaft is 340 feet west of winze No. 1. The ore in this connection is 305 ft. east of the parallel of winzes Nos. 1 and 2. It is authoritatively stated that as soon as this connection is retimbered, which will take about a week, crosscuts will be run to connect with these two winzes. One of these crosscuts will doubtless start from the station at the Union shaft and go to winze No. 1. Winze No. 2 is down but 70 ft. and is progressing slowly, as has also been the drift from winze No. 1 south toward winze No. 2. It is not likely that the crosscut for winze No. 2 will be started from the station of the Union shaft but from the south drift. As winze No. 2 is 270 ft. almost due south of winze No. 1, the crosscut for winze No. 2 would naturally be made from some point south of the Union shaft.

Some speculation is extent relative to the hearing the Union strike has on Sierra Nevada. Of course it increases the chances of that mine. In the first place this connecting drift is further north than was that on the 2400 level. Those who are familiar with the situation will recollect that the incline of Sierra Nevada bears a little north of east. Put that bearing at 5 ft. in descending 100 ft. Then the connecting drift on the 2400 level swung out from the incline station south and rounded to the southwest. This made the line of the connection near the incline 20 ft. south of a right line between the Union shaft and the incline station. The connection made last night is therefore 25 ft. at least nearer Sierra Nevada than was the connecting drift on the 2400 level.

If memory serves aright, a drill was sent from the 2500 station of Sierra Nevada north and west something in the direction of the winze sunk from the 2400 to the 2500 level and which started 135 ft. north of the Union. That drill found from 15 to 20 ft. of milling ore, and beyond that again streaks of ore. If this is so, then there is considerable of a prospect on the 2500 level of Sierra Nevada near the Union line.

In whatever light the recent strike of Union is viewed, it is important. It is an agreeable surprise, and indicates a widening of the ore body to the north, as other touchings of the ore formation show it to be reaching out in other directions.

NEW MINING DISTRICT IN NEVADA.—The *Silver State*, Winnemucca, Humboldt county, Nev., learns from Wm. Graves that while down in Churchill county a few days ago hunting stock, he struck a new mining district of which nothing has been said in the papers. It is situated about nine miles east of the Humboldt salt marsh, and is called Bernico district. The prospectors who had discovered the district had just cut one of the ledges at a depth of 85 ft. from the surface, and were taking out some fine looking ore. They had no opportunity to have it assayed, but ore of a similar character found near the surface assayed from \$193 to \$325 per ton. The formation is slate, with ledges of quartzite, lime and graywacke cropping through. The ore is found under a belt of graywacke, with a talc slate footwall. When the ledge was cut the water broke into the shaft at the rate of about 50 gallons an hour. Another ledge has two ft. of ore which assayed from \$30 to \$285 per ton. It is well defined and looks well. The ore channel appears to be under a large graywacke reef which cuts across the low hill. There are other locations which Mr. Graves did not have time to examine. He says there is plenty of nutpine and cedar wood in the vicinity of the mines, and a fine spring of water. The district is about 85 miles from Winnemucca, which is the nearest station on the railroad, and it will be a good camp if it gets into the right hands.

THE LATEST TORPEDO BOAT.—At Saltonett lake, says the *New Haven Palladium*, two representatives of the Lake Torpedo Company, the manufactory of which is located at Hartford, are engaged in experimenting with one of the company's torpedo boats. The boat is a comparatively recent invention, and the object of the experiments is to improve it in a variety of ways. The boat is made of sheet iron, is about 25 ft. in length and 18 inches in diameter, and is pointed at both ends. The motive power is a screw, propelled by an engine which derives its motion from the generation of gas. The course of the boat is directed from the shore or vessel from which it is sent by means of electricity, paying out wire for the transmission of the electricity as it advances. The explosive power is dynamite, of which 125 pounds are used in loading each boat. Boats of this kind have been sold to the Russian government and to the Peruvian government, and some are in course of construction for the United States government.

A THEORY OF THE WESTERN TORNADOES.—Prof. Tice expresses the opinion, that all such whirlwinds as occasionally sweep the Western States are electrical storms, not wind-storms. There was, he said, no wind attending the Marshfield tornado. Among the evidence of the electrical nature of that storm he notes the facts that it destroyed every building which had a tin roof or which had any metal of any kind in its roof. In Marshfield, it passed directly over several buildings with shingle roofs, and tore to fragments others, not more exposed, which had metal roofs. A mill, situated over a quarter of a mile away from the center of the cyclone, had its iron chimney torn out and carried a long distance, while the mill itself suffered very little damage. The cupola of the public school building at Marshfield, which had a tin roof, was wrecked, but the building, which was roofed with shingles, was not injured to any extent. Even more conclusive and remarkable, he thinks, were the phenomena manifested in connection with trees and shrubbery. The bark was stripped from the trees and hushes not alone on those sides exposed to the force of the cyclone, but on all sides. The ends of the branches were not only denuded of their leaves and bark, but were rifted into fine fibers, so that they presented the appearance of little brooms. The active agent in such cases, he insists, was not wind, but electricity. Under its influence the sap under the bark was instantly converted into vapor or gas, expanding 2,000 times in volume, and as by an explosion, threw off the bark, shattered the trunk and split the green tissue into fibers. That this is what took place is, he says, conclusively proven "by the fact that dead and dry limbs and twigs were not affected, and though in immediate contact with green ones, remained intact".—*Iron Age*.

A STRIKING PROJECT.—One of the most striking projects of this day of remarkable undertakings, is that of closing the straits of Belle Isle, which now cut Newfoundland off from the main land on the north. Through these straits pour the icy current from Labrador which greatly reduces the temperature of the Gulf of St. Lawrence and the maritime provinces, and it is claimed that by filling the narrow channel with rock blasted from the adjoining sides, the climate of the gulf region would be raised to that of France. Another argument urged is the possibility, with the straits closed, of building a railway from Quebec to St. John's at the eastern extremity of Newfoundland, from whence the voyage to Great Britain would, it is claimed, require only five days instead of nine or more, the present time from New York. The latter inducement is rather overdrawn, it strikes us. The fogs and icebergs of the Newfoundland coast would still be dreaded by mariners, as now, and the long and expensive rail journey, extending as far north as latitude 52, where for a large part of the year nature is locked in frost and snow, and through a desolate and unpeopled country much of the way, would not be attractive to our people.—*Railway Age*.

A TRAMP TRAP.—It is a well-known fact that freight cars are a great resort for tramps. These cars afford them traveling conveyance, sleeping apartments, and everything which conduces to make the life of a tramp pleasant and comfortable. To hunt them out or to capture them while in these cars has been one of the great studies of railroad men. One of the most prominent citizens of Colorado Springs has invented what he calls a "tramp trap." It consists of an ordinary freight car, in which is a movable bed resting on spiral springs, something like a spring mattress. To this bed is attached a clutch, which acts on an elliptic spring connected with the doors. The movable bed is adjusted so as not to move until a required weight is upon it—say 1,500 pounds, the average weight of 10 tramps. In this car are placed several boxes of crackers, baskets of wine, boxes of cheese, bundles of cigars, and the doors are left wide open. These articles are soon discovered by the tramps, and they begin to swarm around the car and to enter one by one. When the required weight is in the car the bottom suddenly flies up, throws out the clutch, and the doors close quick as a flash and fasten with a spring lock. The tramps are thus secured until the proper officers come and kill the tramps. We understand the inventor has made application for a patent, and the right to use the same will be placed at a very low figure, as he wants to benefit mankind, and not to make money.—*Railway Age*.

MEADOW LAKE GOLD.—We were shown lately, says the *Truckee Republican* of the 4th inst., a small vial of coarse quartz gold which was taken out of some decomposed rock with a mortar. Judging by the quantity shown us, it must have been very rich rock. There is considerable movement among prospectors now in that vicinity. We learn that quite a number of patents to ground will soon be applied for. Parties from San Francisco and other places are becoming considerably interested in the outlook.

At the head of the Animas river, in Colorado, there is a smooth, bare slope of bright yellow rock, the summit of which is 13,200 ft. high. This is California mountain, and on the crowning ridge stands the Nevada cabin, a house above the clouds, built of the yellow rock of the mountain. It was built in 1876. Numbers of mines are now located clear to the summit of this mountain.

Mines and Mining in Japan.

This is the title of a treatise, says *Iron*, published by the University, at Tokio, Japan. There is no more remarkable incident of the century than the rapidity with which the Japanese are adopting European culture and manners. They have now an army in European uniform, a respectable fleet, a university, their towns are lighted with gas, a railway has for some time united the capital with the chief port, other lines are in progress, and telegraphs are extending as rapidly; books, especially translations from foreign works, are called for on every side, newspapers are being everywhere established, engineering, mining and other industrial questions are attracting attention, and suicide has gone out of fashion. The treatise before us constitutes the second volume of the *Memoire of the Science Department of the National University*. It is printed in better style than similar works issued from the Indian or some colonial presses, the title page is in ornate lithography, and the illustrations are respectfully executed by the same process. When Japan was thrown open to the outer world, great expectations were entertained that its mineral resources, especially in the precious metals, would become a prominent object of commerce; as far, however, as regards the metals these are not now likely to be realized, but coal mining, according to the report, promises a great future. The former chief geologist, in his report on the northern island, Yesso, in 1877, estimates the quantity of the then existing accessible coal at about 150,000 millions of tons, an amount which would enable the island, during 1,000 years, to furnish the coal supply at present derived from this country. It is believed that large deposits of coal exist in the other islands also. The native methods of winning metallic ores are of the most primitive description, although not ineffective; and the author minutely describes these and their metallurgical treatment, together with the furnaces and curious implements in use, giving half a dozen large sheet illustrations of the latter. Iron is chiefly procured from magnetic ore, but its production is as yet very insignificant, not more than 4,800 tons a year. There are several causes for this—the cost of charcoal, the fact that coal and iron do not occur in each other's vicinity, the impossibility of large production by the antiquated processes employed, and the fact that for many purposes the native very soft wrought iron is as useless as the brittle hard cast iron. The import of iron into Japan, both in pig and manufactured, is about 12,000 tons annually; but with the probable construction of railways and the bridging over of the numerous rivers, a considerably increased demand for both descriptions may be anticipated.

FISH HATCHING.—A new interest is added to the marvelous industry of fish-hatching by the discovery that Spanish mackerel can be artificially hatched. The *New York Evening Mail* says that Prof. Earle, who made the discovery, prosecuted his investigations in Maryland; and his enterprise is likely to multiply manifold the supply of our markets with this toothsome fish. While five days are required to hatch shad, and from 8 to 12 days to hatch cod, the Spanish mackerel appear 18 hours after the milk and spawn are brought together, and 200,000 to 300,000 can be turned out at one hatching, while only 20,000 to 30,000 shad can be hatched in one hatch. Another advantage is that the spawning time comes about the last of June, just after that for shad and just before that for cod. It is thus possible to provide for each fish in its season without inconvenience, and the Spanish mackerel will henceforth share with the shad and the cod the attention which Prof. Baird and his force give to the multiplication of the piscatorial population of the United States. As it is expected that 100,000,000 Spanish mackerel will be hatched the first year of the enterprise, it seems impossible to conjecture what proportions the industry of fish hatching will yet reach. The advocates of a fish diet for intellectual purposes must take great satisfaction in Prof. Earle's discovery, and if the stocking of our waters with an abundance of fish of the varieties most sought in our markets can improve the mental faculties of the people, great progress in that direction is to be anticipated.

RAILWAY ALARM WHISTLE.—To prevent the chance of a train running past the danger signal during a fog or snow-storm, without the engine-driver seeing it, the Northern Railway Company of France have recently adopted the plan of having a steam-whistle on the locomotive, worked by a current of electricity controlled by the signal. The whistle is connected with an insulated metallic brush placed under the engine; and between the rail there is fixed a projecting contact-bar faced with copper and 7 ft. long, which is swept by the brush when the train passes. This contact-piece is connected to the positive pole of a voltaic battery, the negative pole of which is in communication with a commutator on the signal-post, from which a wire leads to the ground. So long as the signal is at a "line clear," the passage of the brush over fixed contact produces no result; but when the signal is set to "danger," the commutator brings the negative pole of the battery in direct communication with the ground, and on the brush passing over the contact, completes the electric circuit, and causes the whistle to be sounded, thereby alarming the driver.—*Universal Engineer*.

Cash and Credit.

The marvelous thrift of France is attributable in part to the aversion of the people to debt, as well as to their proverbial economy. Public sentiment in that prosperous country pronounces the failure of a person to pay his debts a stain upon the family name, and where such a sentiment exists, there is much caution about incurring pecuniary obligations. One of the great curses of this country is undoubtedly the credit system, which is the parent of nine-tenths of the bankruptcies, and more than anything else causes the poverty of mechanics and farmers. Could the masses of the people be induced to restrict themselves to the pay-as-you-go system, denying themselves whatever cannot be paid for in cash on the spot, the reformation would sweep away half the ills from which the nation suffers, and 20 years hence bankrupts and almshouses would be almost unknown. If evidence in figures of the disastrous influence of the credit system is demanded, let the statistics of Dun, Barlow & Co. be studied, showing that merchants lost in bad debts an average of \$5,000,000 a week during 1878, and of \$1,250,000 a week during the last six months. These figures should burn in the minds of merchants who have adopted the credit system, and they should suggest to consumers the fact that the prices they pay are made large enough to bear a percentage of these bad debts. The man who steps up to the counter with cash in his hand can invariably buy at lower figures than the man who asks for credit. And the trust system is a snare to purchasers, in that it keeps the question of pay in the background until the glib-tongue of the salesman has urged upon the customer articles he did not intend and really is not able to buy. It is thus a prolific producer of extravagance. The fact that in the first half of 1880—a half year in which there were fewer business failures than in any other during the whole history of the country—the loss by bad debts was at the rate of \$63,000,000 a year, should lead people to consider whether prudence does not require them to eschew credit and depend wholly upon ready cash, whether in buying or selling.—*N. Y. Evening Mail*.

A SEWAGE STEAMER.—How to dispose of the city refuse to advantage is a problem in New York which has not yet had a satisfactory solution. The present cumbersome and very expensive method is of the most primitive kind, which must soon be superseded, in the nature of things, by improved appliances. The corporation of Liverpool has adopted a steam dredger which is proven to be a success in every respect, and we have reason to believe it has received the attention of the New York Pilot Commissioners, and others entrusted with the duty of preserving the harbor. The vessel is of 500 tons, 140 ft. in length, 23 broad and 11 ft. in depth, especially constructed for the economical and speedy conveyance of city refuse for deposition in the deep sea. The new vessel differs from the Clyde hopper steamers in having a hull wider at the bottom than at the top and divided into five pairs of tanks, with separate doors to each, the latter with balance weights so as to open rapidly for the escape of material. A pump of large dimensions can be used at will to force any light material through the open doors. This craft is believed to be the forerunner of many such steamers, as it is well calculated to promote the sanitary arrangements of all our seaport cities. It is represented as dredging at about half the cost of the old system—the results such as to "silence all objectors." Of course it is not to be expected that an innovation of this character can be brought about without opposition, for those who handle the city refuse have a very sweet thing as it is, and will not surrender without a protest.—*American Ship*.

SEWAGE FARMS IN GREAT BRITAIN.—The report of the judges appointed by the Royal Agricultural Society to adjudicate the prizes in the Sewage Farm Competition in 1879 has been published. This report shows that there are about 100 sewage farms in operation in Great Britain. Where market gardening is in vogue the gross returns per acre are largest, and also the amount of wages paid per acre. The gross returns per acre for Leamington appear small. This is due to a large acreage of grassland. When, however, the gross returns per head of the population contributing to the sewers are considered, Leamington comes out in a more favorable light; but, here again, the large acreage absolutely increases this amount beyond its true value. A large area of ordinary agricultural land attached to a sewage farm does not always add to its profit. In the conclusion of the report the sanitary aspect of sewage farming is considered. Among the persons either living or working on the farms, the rate of mortality, on an average, does not exceed three per thousand per annum. This, it is added, is a very low rate, but, in all probability, it may not be lower than would be found in an equal number of selected lives, taken from an agricultural district. The result shows that sewage farming is not detrimental to life or health.

FLOODING THE SAHARA.—The prospects of the several projects for flooding the Sahara are gradually proving small and beautifully less, and at present may be said to have been shelved to make way for railway projects from Algiers and elsewhere into Sudan. As there is no question respecting the feasibility of these last named schemes, there is some probability that they may ultimately be executed.

Manufacturing Industries of San Francisco.

Their Value, Number and Employees.

We give below a list of the various manufacturing industries carried on in the city of San Francisco, together with the value of the manufactured articles, and the number of hands employed. The statement has been prepared from the report of Assessor Badlam, as filed with the Board of Supervisors:

Artificial stone factories, 2; men employed, 115; value of manufactures, \$300,000.
 Axle grease, 2; men, 10; value, \$37,000.
 Barrels, 3; men and boys, 175; value, \$211,000.
 Bags, 6; men, women and boys, 207; value, \$1,903,000; number of bags made, 13,107,700.
 Bed springs, 3; men, 25; value, \$18,000.
 Bedsteads, 4; men, 200; value, \$150,000.
 Bellows, 2; men, 12; value, \$32,000.
 Bedding, 7; men, 325; value, \$78,000.
 Billiards, 3; men, 20; value, \$25,000.
 Boot and shoes, 56; men, 2,700; value, \$1,675,000.
 Boxes (wooden), 0; men, 240; value, \$412,000; paper boxes, 5; men, 60; value, \$42,000; cigar boxes, 3; men, women and boys, 144; value, \$110,000.
 Brass foundries, 8; men, 200; value, \$510,000.
 Breweries, 33; men, 310; value, \$2,100,000.
 Brooms, 14; men, 80; value, \$150,000; handles, 2; men, 10; value, \$12,000.
 Brushes, 3; men, 30; value, \$72,000.
 Candles, 4; men, 140; value, \$450,000.
 Clothing, 12; men and women employed, 4,200; value, \$3,150,000.
 Cigar factories, 200; men, women and boys employed, 3,200; cigars made annually, \$2,500,000; cigarettes made annually, 0 000,000.
 Cement pipes, 2; men, 170; value, \$350,000.
 Crackers, 4; men, 130; value, \$1,120,000.
 Chemicals, 3; men, 35; value, \$800,000.
 Cigarage and cigar boxes, 30; men, 180; value, \$330,000.
 Coffee and spice mills, 10; men, 130; value, \$1,107,000; lbs. of coffee roasted, 5,700,000; chocolate, 327,000 lbs.
 Corsets, 4; men, women and boys employed, 20; value, \$15,000.
 Coffins, 4; men, 30; value, \$110,000.
 Cordage and rope, 1; men, 110; value, \$550,000.
 Carriage springs, 1; men, 17; value, \$50,000.
 Cutlery, 2; men, 35; value, \$50,000.
 Dry docks (floating), 2; men, 15; capacity, 2,000 tons.
 Steam docks, 1; men, 6; cost, \$675,000.
 Electric works, 2; men, 40; capital, \$100,000.
 Fringe factories, 5; men and women, 52; value, \$75,000.
 Flour mills, 3; men, 75; 170,000 barrels of flour are made and 40,000 tons of meal, and 5,300 lbs. of Graham flour.
 Foundries, boiler and iron works, 15; men, 1,200; value, \$3,210,000.
 Furs, 6; men, 55; value, \$270,000.
 Furniture, 18; men, 1,400; value, \$1,650,000.
 Gas works, 1; men, 400; capital stock, \$10,000,000.
 Glass works, 1; men and boys, 150; value, \$175,000.
 Glass cutting, 2; men, 18; value, \$50,000.
 Gloves, 5; men and women, 230; value, \$200,000.
 Glass, 2; men, 15; value, \$100,000.
 Gold refineries, 2; men, 50.
 Gutta percha and rubber, 1; men, 9; value, \$16,000.
 Hata, 18; men, 100; value, \$310,000.
 Hose, 5; men, 25; value, \$200,000.
 Harness, 50; men, 350; value, \$100,000.
 Ink, men, 9.
 Ice, 3; men, 350; value, \$90,000.
 Japanning and galvanizing, 2; men and boys employed, 10; value, \$21,000.
 Lead and shot, 1; men, 140; value, \$700,000.
 Lead and smelting works, 1; men, 110; value, \$700,000.
 Laths, 2; men, 10; value, \$22,000.
 Linseed, 1; men, 00; value, \$715,000.
 Macaroni and vermicelli, 5; men and boys, 33; value, \$140,000.
 Marble, 20; men, 220; value, \$550,000.
 Matches, 8; men, 60; value, \$50,000.
 Malt houses, 6; men, 50; value, \$700,000.
 Mirrors, 2; men, 0; capital, \$150,000.
 Musical instruments, 2; men 16; value, \$10,000.
 Oil clothing, 4; men, 20; value, \$10,000.
 Oakum, 1; men, 20; value \$40,000.
 Pickles and fruits, 11; men and women, 1,700; value, \$1,000,000.
 Powder works, 2; men, 62; value \$900,000.
 Pumps, 2; men, 16; value \$90,000.
 Rolling mills, 1; men, 310; value, \$1,104,050.
 Salt works, 3; men, 47; value, \$190,000.
 Safe and vault, 4; men, 40; value, \$60,000.
 Saws, 1; men, 30; value, \$100,000.
 Sashes, blinds and doors, 15; men, 1,400; value, \$4,500,000.
 Silverware, 3; men, 50; value, \$150,000.
 Shirts, 20; men and women, 1,000; value, \$500,000.
 Slippers, 25; men and women, 1,000; value, \$470,000.
 Soap, 21; men, 300; value, \$2,370,000.
 Sugar refineries, 2; men, 200; value, \$6,035,000.
 Tanneries, 43; men, 330; value, \$1,650,000.
 Tools, 11; men, 75; value, \$160,000.
 Type foundries, 2; men and women, 46; value, \$50,000.
 Vinegar, 2; men, 20; value, \$150,000.
 White lead factory, 1; men, 75; capital, \$250,000.
 Windmills, 2; men, 10; value, \$22,000.
 Woodenware, 1; men, 40; value, \$200,000.
 Willowware, 2; men, 8; value, \$6,000.
 Woolen mills, 1; men and women, 700; value, \$1,500,000.
 Wire rope, 1; men, 38; value, \$240,000.
 Wire works, 2; men, 40; value, \$60,000.

A COLD AIR MOTOR.—A novelty in motive power, consisting of an engine set in motion by air combined with steam, is now on exhibition in New Street. The invention consists of an attachment very much like a common air pump by which cold air is forced by the engine into the steam cylinder. The increase in the number of revolutions per minute of the fly-wheel, when this apparatus is applied, over the number it is able to make when the engine is run by steam alone, seems to indicate a great gain in power. A 10-horse power stationary engine is used to exhibit the appliance. The exhibitors claim that with this invention they can do 10% more work on 30% less coal, or in other words, that its use will effect a net saving of 37% in the cost of running an ordinary engine. On June 15th, with 385 pounds of coal, and while using a friction brake weighing 168 pounds, the engine with steam alone caused the fly-wheel to make 18,688 revolutions. On the next day, with the apparatus attached, but with only 270 pounds of coal—all other conditions being equal—the fly-wheel made 20,793 revolutions. For the purpose of thorough inspection by all who may be interested, the engine and appliance will be on exhibition in running order for some time. Engineers are particularly invited to test the truth of the exhibitor's statement.—*N. Y. Herald.*

USEFUL INFORMATION.

Useful Recipes.

To Clean Marble.—Marble, soiled from ordinary use, can be nicely cleaned in the following manner: Pulverize a little bluestone, and mix with four ounces of whiting; add to these four ounces of soft soap and one ounce of soda dissolved in a very little water. Boil this preparation over a slow fire 15 minutes, stirring all the time. Lay it on the marble while hot, with a clean brush. Let it remain half an hour; then wash off in clean suds, wipe dry and polish by quick rubbing. Marble which has become soiled from smoke may be cleaned as follows: Moisten powdered quicklime with a strong solution of washing soda in hot water; brush this over the stone and let it dry. Brush off, wash with plenty of water, and polish with a little tripoli.

Oil Marks on wall paper, or the marks where inconsiderate people rest their heads, are a sore grief to good housekeepers, but they can be removed without much trouble. Take pipe-clay or fuller's earth, and make it into a paste, about as thick as rich cream, with cold water; lay it on the satin gently, without rubbing it in; leave it on all night. It will be dry by morning, when it can be brushed off, and unless an old stain, the grease spots will have disappeared. If old, renew the application.

GREASE on a carpet, if not of too long standing, can be readily disposed of by washing the spot with hot soap-suds and borax—half an ounce borax to gallon of water. Use a clean cloth to wash it with, rinse in warm water and wipe dry.

To Take Out Ink from Woolens.—If ink is spilled on a carpet or woolen article it should be attended to at once while still wet, if possible, and then is very easily removed. Take clean blotting paper or cotton batting and gently sop up all the ink that has not soaked in. Then pour a little sweet milk on the spot and soak it up from the carpet with fresh cotton batting. It will need to be renewed two or three times, fresh milk and cotton being used each time, and the spot will disappear. Then wash the spot with clean soap suds and rub dry with a clean cloth. If the ink has been allowed to dry in, the milk must remain longer and be repeated many times.

LUMINOUS FLOWERS.—Among the elegant novelties of the hour offered for sale on the Paris boulevards are phosphorescent flowers, which glow with a lambent light in the dark, and almost rival their natural tints. They are rendered luminous by coating the petals with transparent size, and then dusting them with a phosphorescent substance, such as Canton phosphorus (sulphide of calcium) or Bologna phosphorus (sulphide of barium). Canton phosphorus is the best, and yields a soft yellow light. According to M. Bequerel, a good quality can be made by mixing 48 parts of flowers of sulphur with 53 parts of calcined oyster shells, and raising them to a temperature of between 800° and 900° centigrade in a crucible. After exposure to sunlight during the day, or to the electric or magnesium light, the flowers thus coated become brightly luminous in the dark.

LEAKS IN GAS PIPES.—To detect leaks in gas pipes, it is recommended to apply soap suds to the suspected leaky joint. The formation of bubbles will show an escape. This is safer than trying the joint with a lighted match. If the leak occur in the branch of a bracket or chandelier, it is repaired by soldering with plumbers' fine solder; if it be a very small one, beat the piece first, with a spirit lamp, and fill the aperture with cement.

THE Pullman sleeping car monopoly is on the wane. It has had its day as an absolute monopolist in this particular business. Many of the leading railway propose to do their own palace and sleeping car business, an announcement that will be hailed with joy by a patient yet long-suffering traveling public.

RAILROAD PATENTS.—Of 279 patents issued during the week ending July 6th, 22 were inventions especially intended for railway use. The number of railway patents issued each week ranges from 10 to 30, a fact which must leave no room for fear that progress in that direction is not keeping pace with other material interests. A large majority of these, however, possess little or no real value.

ODOR OF DINNER.—Most people do not care to inhale the odor of the vegetables which are being boiled for dinner; but in confined city houses it is not easy to prevent the evil. But now a scientific writer authoritatively says that a piece of bread about the size of a French billiard ball tied up in a linen bag and inserted in the pot with the greens will absorb all those gases which disseminate such insufferable odors.

ON THE HALF SHELL.—Mr. K. M. Cunningham suggests a quick way of getting marine diatomaceæ: by taking a peck of fresh oysters and brushing the back of each into a basin of water, this process will give pleurosigma and coccinodisci in abundance.

IVORY that has been spotted, or has grown yellow, can be made as clear and fresh as new by rubbing with fine sand paper, and then polishing with finely powdered pumice stone.

Color Changing Compounds.

The double iodides of silver and mercury and of copper and mercury are perhaps the most remarkable known to chemists in respect to their color sensitiveness when exposed to moderate changes of temperature. They were first described and their peculiar properties pointed out by Meusel, a German chemist. The first is prepared by adding a solution of nitrate of silver to one of iodide of mercury, dissolved in iodide of potassium. The resulting precipitate has a lemon-yellow color, which becomes at once a deep orange when gently warmed, returning again to a bright yellow on cooling.

The copper-mercury iodide, which is still more remarkable, is prepared by adding to a warm solution of iodide of mercury in iodide of potassium some sulphate of copper and then sulphurous acid. The precipitate is a brilliant carmine-red salt which turns brown, and finally an intense black on being gently heated—returning again to carmine on cooling. These changes occur within the limits of 60° and 212° Fahr., and may be easily and strikingly exhibited as a lecture experiment, by mixing the precipitates with a little water (to which some mucilage may be added) and attaching a thin coating of each to a piece of card-board. A number of instructive experiments may be performed with them. A piece of slightly-heated metal, held for an instant in contact with the card, or close to it, will at once bring out an image of itself—a veritable heat-photograph. Many other striking experiments will suggest themselves to our chemical readers.

Messrs. Mayer and Barker have prepared the carmine salt as an application to pillow blocks and other parts of machinery liable to injurious heating, where it will exhibit its characteristic color changes to the eye should any excessive heating take place.

ARTIFICIAL INDIGO.—It is reported that Prof. Bacyer, whose researches in the direction of the artificial production of indigo have made him famous, has discovered a method of obtaining artificial indigo on the commercial scale. The process is reported to have been patented, and the patent has been assigned to the Baden Aniline Co. The indigo is obtained from isatin chloride which in turn is produced from benzole.

TO CLEAN VELVET.—When velvet has been wet and becomes spotted, hold the wrong side oversteam, and while damp draw the wrong side quickly over a warm iron. It takes two to do this—one to hold the bottom of the iron upward, and the second to draw the velvet across.

GOOD HEALTH.

Heart Affections.

There is not a pin's point surface of the external portion of the body which does not give instantaneous warning of the slightest invasion from without: It is our guard against external dangers. But the more important internal organs are so well protected by the casings which surround them, that they do not require such sensitiveness; hence it is not thrown away upon them. For example: It is generally supposed that if the heart is touched we would die instantly. So far from this being true, bayonets and bullets have been driven into the heart of men and animals without causing death. The bullet which caused the death of William Poole was found imbedded in the solid substance of the heart, and yet he lived 11 days after he was shot.

The great Harvey brought Charles II. to a British nobleman who had an opening in his chest, through which the heart could be seen and felt. The king touched it with his finger, but the nobleman was not aware of it, unless he saw the fingers in the cavity. And yet this same heart responds to every emotion of joy, or grief, or passion, or alarm.

Persons often trouble themselves uselessly, about having disease of the heart or lungs, because they have pain thereabouts. These are good signs, generally, as showing that the pains are external to these organs, for there can be no pain where there are no nerves. The fact is, the most certainly fatal affections of these organs give no note of warning by pain, until within the last brief hours of life. The very substance of the lungs and heart are often eaten through, eaten away, without a remote suspicion on the part of the patient that such was the case. The celebrated clerical orator, John Newland Maffitt, died of a literally broken heart—not an emotional breaking, but a structural rupture; it had slowly decayed, rotted away, until so near through that its functions could not be performed, when pain came on, and he died in a few hours; on examination, it was found that this destruction of parts had been going on for months, most probably.

But another result follows the closing of the pores of the skin, and more immediately dangerous. A main outlet for the waste of the body is closed, it remingles with the blood, which in a few hours becomes impure, and begins to generate disease in every fiber of the system. The whole machinery of the man becomes at once disordered, and he expresses himself as "feeling miserable." The terrible effects of checked perspiration on a dog, who sweats only by his tongue, is evinced by his becoming "mad." The water runs in streams from a dog's mouth in summer, if exercising

freely. If it ceases to run, that is hydrophobia. It has been asserted by a French physician that if a person suffering under hydrophobia can be only made to perspire freely he is cured at once. It is familiar to the commonest observer that in all ordinary forms of disease the patient begins to get better the moment he begins to perspire, simply because the internal heat is passing off, and there is an outlet for the waste of the system. Thus it is that one of the most important means for curing all sickness is bodily cleanliness, which is simply removing from the mouths of these little pores that gum, and dust, and oil which clog them up. This it is, also, that personal cleanliness is one of the main elements of health—thus it is that filth and disease habitate together the world over.

The great practical lesson which we wish to impress upon the mind of the reader is this: When you are perspiring freely, keep in motion until you get to a good fire, or to some place where you are perfectly sheltered from any draft of air whatever.—*Hall's Journal of Health.*

Checked Perspiration.

This is a fruitful cause of sickness, disease and death to multitudes every year. If a tea-kettle of water is boiling on the fire, the steam is seen issuing from the spout, carrying the extra heat away with it, but if the lid be fastened down and the spout be plugged, a destructive explosion follows in a very short time.

Heat is constantly generated within the human body, by the chemical disorganization, the combustion, of the food we eat. There are seven millions of tubes or pores on the surface of the body, which in health are constantly open, conveying from the system by what is called insensible perspiration, this internal heat, which having answered its purpose, is passed off like the jets of steam which are thrown from the escape-pipe, in puffs, of any ordinary steam engine; but this insensible perspiration carries with it, in a dissolved form, very much of the waste matter of the system, to the extent of a pound or two or more every 24 hours.

It must be apparent, then, that if the pores of the skin are closed, if the multitude of valves, which are placed over the whole surface of the human body are bent down, two things take place. First, the internal heat is prevented from passing off, it accumulates every moment, the person expresses himself as burning up, and large draughts of water are swallowed to quench the internal fire—this we call "fever." When the warm steam is constantly escaping from the body in health, it keeps the skin moist, and there is a soft pleasant feel and warmth about it. But when the pores are closed, the skin feels harsh, and hot, and dry.

ALCOHOL AND DIGESTION.—According to foreign medical journals, M. Leven has been investigating the question of the quantity of alcohol which should be taken to facilitate digestion, and, consequently, the assimilation of food. He demonstrates, by conclusive experiments, that an excess of alcohol, as 75 grams of brandy to 200 grams of meat, completely arrests digestion; while 25 grams of brandy with the same weight of meat will, on the contrary, have a very powerful effect on the digestion. The quality of the alcohol used is of no less importance. Dr. Rabuteau has studied the comparative action of the different alcohols of commerce with the greatest care. Ethylic or vinous alcohol has always yielded the best results. His numerous experiments show that even an excess of this kind of alcohol does not produce the injurious effects that are brought on by even moderate use of the majority of the alcohols of commerce, and especially of that variety which contains anylic alcohol. According to him, it is this kind which produces the lamentable results of alcoholism.

METALS IN THE BODY.—The human body, which seems made up of flesh and blood, really contains several metals and gases, and other substances which perform important offices in the world of science. Nitrogen and carbon and hydrogen are its chief constituents, but it holds, besides, about two pounds of phosphorus, which is essential to the health of the bones and vigor of the brain. This phosphorus, if extracted and put to use, would make up about 4,000 packages of friction matches. Beside phosphorus, it contains a few ounces of sodium, and a half ounce of potassium, which school-boys know as a curious metal, that burns brilliantly on the surface of water or when touched by an icicle. The quantity of such in the body would be sufficient for many experiments in a large school. In addition to sodium and potassium, there are a few grains of magnesium, enough to make the "silver rain" for a family's stock of rockets on a Fourth of July evening, or to create a brilliant light visible twenty miles away. Who knows but some reckless chemist may undertake to drive a profitable business by extracting these materials from dead bodies?

VASELINE.—Vaseline, or petroleum jelly, is one of the most useful substances for external use ever brought to the attention of the medical profession. Being neutral, bland and unchangeable, as a mere lubricant, or as a basis in the preparation of ointments and liniments, it deserves to supplant all animal fats and oils. And for the toilet, whether alone or in combination with aromatics, for the choicest pomades and soaps, it excels all other substances in elegance and exemption from injurious properties.—*Sanitarian.*

Business Announcements.

Assessment Notice—Gover M. & M. Co.
Dividend Notice—Con. Virginia M. Co.

The Week.

The most noteworthy incident in this city during the week was the opening of the Fifteenth Industrial Exhibition under the auspices of the Mechanics' Institute. The usual exercises were held at the Grand Opera House in the presence of a great concourse of our people. The admirable address of President Cornwall, which we print in full elsewhere, sketches the rise and growth of the Mechanics' Institute, the details of which are as interesting as they are remarkable. Hon. A. A. Sargent delivered the oration on "Industrial Progress," a full report of which will appear in our next issue. At the Pavilion in the evening the exhibition opened to a very fair audience for the first night. The display was, of course, in some features, in a state of unreadiness; but that defect is being corrected daily, and the managers are pushing their arrangements for an early and complete exhibition in all the departments. Many agreeable changes have been made in the Pavilion, and besides its great interest to those concerned in business affairs, it daily offers delightful attractions to the young and to the merely curious.

On Wednesday, the 12th inst., Capt. James B. Eads appeared by invitation before the Chamber of Commerce, and gave a comprehensive description of the plan and estimated cost of his proposed marine railway across the Isthmus of Darien. Mr. Eads fairly met every objection to his scheme; contrasted his railway to the De Lesseps canal, and ably maintained the superior advantages of the former. Among other propositions, Mr. Eads stated (1) that a ship railway can be constructed at one-half the cost of a canal with locks and in one-half the time; and (2) that when completed the railway can be maintained and operated at a cost not exceeding that of a canal.

Accounts from the mining regions continue to be satisfactory. Operations in the gravel and placer mines of this State have been generally successful, and at many of the claims the yield of gold has been large. Gold quartz mining has been unusually active all the season, and there are no signs of this interest abating. The revival in mining in this State has reacted favorably on the general business, and this outlook for a prosperous year is excellent.

The situation on the Comstock continues to

be encouraging, although no incident of special importance has occurred since our last. The indications of a coming development at this north end have fortified the waning confidence of the market, and there is a decided feeling that there will soon be an improvement.

Left-Handed Objections.

We agree with the New York *Mining Record* that Mr. Kustel's handbook on the "Roasting of Gold and Silver Ores" is one of "the best known books in American metallurgical literature." Its notices of the little work, however, appears to have been done carelessly, and, what is singular, somewhat hypercritically. In the first place, we may remark that the title of this book is not a "misnomer," for it treats distinctly of the various means and methods of roasting the ores of gold and silver through about two-thirds of its 156 pages. In fulfillment of the promise of the title-page, the book also treats of the methods employed in extracting those metals without the use of quicksilver; there being a chapter on the extraction of silver by the process of lixiviation, and another on the extraction of gold from various combinations of minerals by chlorination. The scope of the work is somewhat larger than its compact title indicates; it might be fuller; but it is neither a misnomer nor misleading. If on opening the book one is surprised at finding a larger measure of information than he sought, the surprise will be wholly agreeable.

There is also an objection to Mr. Kustel's use of the term roasting, which is employed, says the writer, "to cover all kinds of roasting, both with and without salt." Surely the salt of this criticism is without savor. Ores are subjected to either a chloridizing roasting or an oxidizing roasting; in both cases it is a method of roasting, is it not? The book gives a very full account of this process of chloridizing roasting, and an ample one of oxidizing roasting; and in both cases the details of the manipulation are so complete that we cannot imagine how even a reader below the average could possibly "find himself often in doubt or ignorance of what the author means to tell him."

Finally, while the writer approves on the whole of the chemistry of Mr. Kustel's book, he objects to the statement that "the decomposition of superheated steam is a source of heat." What Mr. Kustel says (page 19) in relation to this matter is: In the Hagan roasting furnace "the decomposition of superheated steam is a source of creating heat and a decomposing agent at the same time." Mr. Kustel shows that the Hagan furnace is a shaft or vertical furnace in which the superheated steam is forced directly on the fuel and ore. A large percentage, or all of the superheated steam, is decomposed, and its oxygen combines with the glowing carbon of the fuel and forms carbonic acid and carbonic oxide. This describes the art of oxidizing the carbon; oxidizing means burning; and the burning of carbon creates heat. In reading Mr. Kustel's book we have not discovered that he lays too much stress on the application of steam in roasting silver ores. Nevertheless, we find on page 33 that he offers apparently good reasons for its use under certain conditions. It is to be observed, as Mr. Kustel points out, that considering the percentage of moisture contained in the fuel, there is no roasting done without the presence of a limited quantity of steam. We fail to perceive that the manner in which Mr. Kustel has treated the application of steam in roasting certain ores is in any degree a "hlemish." On the whole, so little has been said by the writer, and that little is so kindly careless, that we accept it as a valid, though not hearty approval of a work of large merit.

JACKSON COPPER MINE.—Mr. D. H. Jackson, the owner of a remarkable copper mine near Walker river, says this *Territorial Enterprise*, has brought into Virginia some very fine specimens of this ore, which yield from 50% to 60% copper. There is a mountain of ore and native bluestone (sulphate of copper) on the surface. From the bottom of a shaft 100 ft. in depth he is now drifting east in a solid mass of ore of the richest character. In his office in this city is to be seen a pile of igneous of pure copper, weighing in all 1,600 pounds. This copper was smelted in a furnace of the rudest description. The Jackson copper mine would create a sensation in the Lake Superior country, where it would probably sell for half a million dollars at the drop of a hat. If we could send all our lead mines to Galena, Ill., and all our copper mines to Lake Superior, we would doubtless do well with them.

ALTITUDE OF BODIE MINES.—Next to the lofty mines of Colorado those of Bodie will take rank for their elevation. We believe they are the highest on the Pacific coast of the U. S. A table of altitudes in Bodie has been compiled by C. L. Anderson, M. E., his computations being in accordance with the formula of the U. S. Coast Survey. From this table it appears that the works of 29 mines are at an altitude ranging from 3,623 ft. to 9,336 ft. The greatest elevation is that of Mount Beidelman, four miles west of Bodie, which reaches 10,336 ft. The theory has been advanced among others, by some New York mining experts, that altitude was a necessary feature of an enduring mine, whether of gold or silver. Accepting this theory, it must be admitted that Bodie fully meets that requirement.

Letters from the Comstock.—No. 7.

EDITORS PRESS:—While it takes but a trifle light as air to knock the market to smithereens, another trifle will infuse a wonderful amount of hackhons into it. Recently a few streaks of ore were discovered on the 2500 level of the Union, and presto! the laggard holders, the faint and weedy dealers, and the sick of heart spring once more into the pool of speculation, and are ready to go in over their heads at the first plunges. The coming upon this ore simultaneously from three sides of a triangle, was as much of an astonishment to the managers as any body. Mr. Mackay, two days before, said positively that there was no prospect there. Your correspondent is of the opinion that this ledge is turned aside from its regular course, and by this turn has eluded pursuit; is a hare doubtless, on its course, and sends this hounds scurrying ahead on a lost scent. Some mighty force, coming down the mountain side, has accomplished this change of formation. One sees signs of the elbow near the incline of the Sierra Nevada, a little north of it, on the 2500 level, but bends to the left looking north. The formation of the upper earth is quite diverse from the lay of the ground anywhere else on the lode. The pitch of the hills is steeper and there is a sort of basin. The depression is very marked, and the ledge does not lie under the slope of the hill, as in the other mines south. What these surface formations indicate is more than your correspondent, who is utterly at sea in geology, can tell; but there is every reason to believe that a convulsion of nature which leaves such pronounced marks on the surface would make its impress lower down. This being the case, the theories which held good south of Ophir would be at fault in the north, and the unexpected encounter with the stringers of ore, and in fact a portion of the ore-body such as found in Union last week, hears out this idea. Prof. Stewart laid considerable stress upon the surface formations of the north end as indicating a broken condition of the ledgs. This was many months ago, and his theories were not generally accepted. Perhaps they will give the old Professor his due when he comes back. It is not improbable that ore bodies will be found in this locality quite distinct from the main ledge, carried by some force a considerable distance, and lying in detached blocks, or, as Dan De Quille very well expresses it, "like plums in a pudding." While cheery indications in Union have traced the north end quite noticeably, there is also a speck of hope in the horizon for Sierra Nevada. On the 2400 level a drill has been run east, and encountered a formation which assays from \$6 to \$18, if the reports are to be believed.

On the 2800 level of the Imperial a crosscut has been started 100 ft. north of the south winz, which is in favorable quartz formation. Work on the face of the Belcher drift has been resumed. On the 1300 level of the Savage, low-grade ore is being found, but in small quantities. With all the indications and theories, however, the knowing ones do not look for a real lively market until the senatorial fight waxes warm. If Fair joins issues with Sharon, stocks will be worth the having. **HAND DRILL.**

BODIE'S BULLION PRODUCT.—The following detailed statistics of the amount of bullion produced in and shipped from Bodie, were furnished to the editor of the *Stock Report* by the agent of Wells, Fargo & Co. The showing is excellent, and is far beyond the general impression of the product of this district. The period embraced in the statement is from 1877 to June 30, 1880:

Standard Con.....	\$4,135,676.94
Bodie Con.....	1,995,657.41
Bedchtel Con.....	71,699.98
Red Cloud.....	10,927.50
Sitting Bull.....	3,485.09
Mexican.....	2,000.00
Summit.....	1,500.00
Syndicate.....	12,316.33
Bulwer.....	341,964.81
Woodward.....	235,232.85
Miscellaneous.....	90,567.37

Grand Total.....\$6,901,008.03

The product of Standard Con., and other mines in the district, since the close of June to date, bring the grand total to upwards of \$7,000,000. This handsome sum has been produced within three years, with a milling capacity during two years of the period of only 55 stamps. The present promise of Bodie is for a largely increased product.

A PROPER INDICTMENT.—At New York on Tuesday, the 10th inst., the Grand Jury in the U. S. Court made a presentment in the case of the steamer *Seawanhakha*, which was burned in the East river some three weeks, the disaster being attended with frightful loss of life. The Grand Jury says it believes the disaster was due to criminal carelessness and negligence on the part of certain Government officials and the officers and owners of the vessel, and attached to the report were indictments against those parties. The offenses charged against them is manslaughter, and hence warrants have been issued for their arrest. Certified copies of the presentment have been sent to the President, the presiding officers of the Senate and the House of Representatives, the Attorney General and the Secretary of the Treasury.

Specifications of the Yuba Dams.

The following specifications of the Stats Engineer for the construction of the dams over the Yuba river are from the Wheatland (Yuba) News:

The upper dam upon the Yuba is nine and one-quarter miles above Marysville. The distance across the river bed is about 4,800 ft. The dam is to be erected eight ft. high above the general plane of the bed, and from four to 12 ft. above the bed, according to its elevation. At each end the dam is to slope upwards until it reaches an elevation of six ft. above the level top of the center. On the north side the end will be set in a bench cut into the rocky point, and both ends will be covered and protected by masses of rock. The dam will consist of a down-stream apron and the dam proper. The apron is placed in an excavation of from four to 10 ft. in depth, and consists of horizontal layers of trees from four to eight inches in diameter and 25 to 30 ft. in length, with the brush still on the trunks, placed with the butts down the stream. The layers are separated by poles and the spaces filled solidly with small brush and with gravel, to the extent of 30% of the bulk of the structure. The poles and layers of trees are to be fastened firmly together with iron spikes or wooden pins. The surface is slightly below the level of the channel. Resting upon its upper edge are trees with the butts down stream, but each layer resting up stream and separated and fastened as described. Resting partly upon the upper edge of this, and partly upon the level of the sand, is the dam proper. It consists of first of layers of trees from 14 to 18 ft. in length, with the butts down stream, inclining at an angle of 45° to the up-stream bed and built up to the full height of eight ft., the exposed butts forming the lower face of the dam and sloping down at an angle of 45°. Upon the rear face of this lie trees from 30 to 35 ft. in length, whose exposed butts form the top of the dam, and whose brushy tops are sunken in an excavation forming the heel of the dam. Finally, upon this is placed either a mass of gravel or of stone fragments. The work is to be done in sections of not less than 100 ft., or more than 200 ft., the excavation in half of each section at least to be complete before any brush is laid. The trees are to be cut below the dam, but at every 500 ft. a belt must be left across the stream as far as it goes. Fascines or bundles of brush bound together with wire may be used where sufficient trees cannot be found within 2,000 ft. of the dams. Bids will be received for excavation, brush and timber ballasting, gravel backing, stone backing, stone weighing and protecting, and earthwork embankment. The second dam upon the Yuba is two miles below the first, and about 9,600 ft. in length. This work is about the same as on the first. The dam on Bear river starts from a point some 200 ft. above the end of the levee at Johnson's crossing. It will be about 6,000 ft. in length. The specifications of the second Yuba dam apply to it completely.

North American Review.

The August number of this substantial monthly presents an interesting and valuable table of contents. The opening paper by the editor on the "Ruined Cities of Central America," will not fail to awaken the liveliest interest of the general reader to know something more of a race which has left behind it such splendid monuments of its vigor and cultivation. Our present knowledge of the remains of a wonderful civilization is derived mainly from the works of our distinguished traveler, John L. Stephens. But the expedition under the charge of M. Charnay, which has already gone to Mexico, promises the most interesting revelations regarding the remains of an extinct race. The earliest accounts from the pen of the explorer, illustrated by engravings, will be laid before the readers of the *Review*. Prof. Profitt's "Law of Newspaper Libel" is a highly critical presentation of the subject under the most enlightened law, and will be profitable reading alike to the professions of law and journalism. Richard H. Dana's "Nullity of the Emancipation Edict" is a curious chapter on the most remarkable incident of the civil war. This paper on the "Principle of Taxation," by Prof. Simon Newcomb is a clear disquisition on a very practical subject. The writer's propositions are stated with nice precision, and his conclusions amount to demonstrations. "Prince Bismarck as a Friend of America and as a Statesman," by Moritz Busch, is fascinating reading. The great Chancellor is one of the remarkable men of the century. The article abounds in bits of home conversations and anecdotes, in which the extraordinary character and glimpses of the very heart of this statesman are revealed. His reverence for royalty and his devotion to the royal State are intensely fervent. His religious belief is as firm as the rock. "I have a firm, unshaken faith in a life after death," he exclaims; "therefore, I am a royalist. Otherwise, I should be a republican." Bismarck's statecraft—his statesmanship—as revealed in his own words, is the very refinement of expediency. This fascinating sketch will greatly raise the reader's admiration for the great German. Congdon's "Recent Literature" offers some very manly and graceful criticism. The *Review* is published by D. Appleton & Co., New York, at \$5 a year, or 50 cents a copy.

James B. Eads.

A Brief Sketch of the Life and Remarkable Works of the Great Engineer.

James B. Eads was born in Lawrenceburg, Indiana, May 23, 1820. In 1833 his parents removed to St. Louis, Missouri, in which city he has since resided. Owing to the financial embarrassment of his father, young Eads was compelled to leave school at the age of 13; but he eagerly took advantage of every opportunity that presented itself to increase his information. His diligence in acquiring facts was remarkable; and when he reached manhood his mind was stored with valuable knowledge. The story of the great engineer's life offers a bright example to our American youth. He essayed to have begun his career with a distinct purpose, and permitted no obstacle to turn him aside from its accomplishment. Denied almost every advantage in his early years, he appears to have formed the heroic resolution to succeed in spite of fortune. He formed a habit of systematic discipline, and acquired that methodical application and persistence which have so sharply accented his riper years. Starting in life without either wealth or influence, it may be fairly said that he was the architect of his own fortune.

Perhaps no living engineer has risen to greater prominence in his profession, nor become more widely known than James B. Eads. For more than a quarter of a century he has been engaged in engineering works of the greatest magnitude, and in every instance his success has been complete and brilliant. In order to satisfy the public interest we propose to give a brief history of his life and works.

Young Eads was employed for five years as a clerk in a dry goods store; but the business was not to his liking. Having great mechanical ingenuity and a decided taste for mathematics, his natural bent was towards engineering; and he zealously devoted all his spare time to the study of that and kindred branches of sciences. At the age of 19 he was employed as a clerk on a Mississippi river steamboat; and while in that position he first began to study the peculiarities of the great river and to consider the means involved in its improvement. As early as 1842 he constructed a divingbell boat, designed to recover cargoes of sunken steamers; and soon afterwards he contrived large boats, provided with novel and powerful machinery, for raising the hull and cargoes of steamers which had gone to the bottom. He succeeded by these ingenious contrivances in recovering a number of large and valuable vessels. The operations of the young engineer extended over the entire river and its principal tributaries; and in this way he became familiar with every part of the Mississippi, and formed the theories which he has since demonstrated with such signal success. From his first step young Eads was remarkably self-reliant; indeed, many of his schemes savored of audacity to older engineers. His courage was dauntless. In 1856 he proposed to remove all the wrecks and snags which obstructed the channels of the Mississippi, Missouri, Ohio and Arkansas rivers, and a bill authorizing him to undertake the work passed the House of Representatives in 1857, but it failed to pass the Senate for want of time.

The advent of 1861 and its tremendous events brought opportunity to the active and aspiring engineer. He was requested by President Lincoln to visit Washington to confer with him as to the practicability of constructing iron-clads of light draft for service on the Western rivers. Soon after this conference Mr. Eads designed and built eight iron-clads having a speed of nine knots. This powerful fleet was completed and fully equipped, and ready for its armament of 107 guns, within the period of 100 days. But the invincible energy of the engineer was commensurate with his splendid ability. These iron-clads were the first war-vessels constructed by the Government, and some of them were engaged in the capture of Fort Henry, more than a month before the memorable contest between the *Monitor* and the *Merrimac*. In 1862-3 Mr. Eads designed and constructed six turreted iron-clad vessels, all of which were heavily plated. The turrets were of novel construction, and their powerful 11-inch and 15-inch guns were worked by steam, and could be loaded and discharged in 45 seconds. This was the first instance where steam-power was used in the manipulation of artillery.

We now approach the period of Mr. Eads' most brilliant achievements. In the interval between 1867 and 1874 he designed and erected the St. Louis bridge, which in many respects has no parallel in the world. In a paper recently read before the British Institute of Civil Engineers, on the "Recent Progress in Engineering," the first place is assigned to that work as the greatest engineering feat accomplished during the last half century. At the time the work was undertaken, grave doubts were expressed as to the practicability of the project, and few men, either in this country or abroad, would have taken hold of so stupendous a work under the circumstances which surrounded it at its inception. It was a supreme task, and it demanded the indomitable perseverance, rare engineering skill, amazing capacity for work, and perfect self-reliance of James B. Eads. He met and overcame every difficulty, and finally, by incessant application and severe work, he accomplished his purpose, and erected one of the grandest bridges of modern times.

The bridge is built of steel. Its central arch has a clear span of 520 ft. and the side arches

have each a span of 502 ft. The piers all rest on the solid rock underlying the river deposits, and two of them are much deeper than any constructed prior to that time. One of these piers, weighing 45,000 tons, was sunk 136 ft. below high water mark, through 90 ft. of sand and gravel; and another, weighing 40,000 tons, was sunk to almost as great a depth.

During the progress of the work many demands were made upon the mechanical skill of Mr. Eads, and many were the devices which he originated and applied in overcoming the difficulties which presented themselves. Among the devices employed were those connected with the construction of the caissons for sinking the piers through the sand to the bed rock. These improvements were afterwards adopted in sinking the deepest pier of the East river suspension bridge.

The arches of the St. Louis bridge were built out from the piers until they met at the center. The half spans near the shores of the river were supported by iron guys passing over temporary towers on the piers and anchored securely on shore. At the central piers the half spans balanced each other, being built out from opposite sides of each pier. The arches are composed of four curved ribs with top and bottom booms formed of steel tubes 18 inches in diameter and strongly braced about 12 ft. apart. As a whole, and in detail, the bridge is a noble and imposing structure.

Mr. Eads had long had in view the project of opening the mouth of the Mississippi river to the commerce of the world. The accomplishment of this project promised enormous benefit to the great Mississippi valley. It was proposed by the United States engineers to

large expenses involved in the canal scheme. The estimated cost of the work was \$12,000,000; it would probably have reached \$20,000,000. Mr. Eads showed conclusively that the canal could not be completed before 1881. He also urged upon Congress the consideration that the canal when completed would afford an adequate relief to the commerce of the river. Finally Mr. Eads made a proposition that was startling in its audacity. He proposed to give an open river mouth to the commerce of the world—a broad, deep, unobstructed channel—for the sum of \$5,250,000; stipulating that not one dollar of this sum should be required of the Government until he had secured a channel not less than 20 ft. deep and 200 ft. wide. This amazing proposition was in direct antagonism to the unanimous recommendations of the U. S. Engineer Corps—a body of men known to be able and eminent in their profession. Mr. Eads not only proposed to depart from long established precedents in engineering, but to assume the enormous financial risks involved in carrying out such a vast public work. The proposition was worthy of the strong, self-reliant engineer.

The result of Mr. Eads' proposal was, that Congress postponed the canal project and appointed another commission of engineers to reconsider the whole matter and report thereon. The new commission comprised three engineers of the U. S. army, three civil engineers and one from the coast survey. This board went abroad during the summer of 1874 and examined many noteworthy works—among others, the jetties at the mouth of the Danube. The board then returned home and made another very careful examination of the mouth of the

desper and winner over its entire length, and now exceeds greatly the requirements of the law. For securing this harbor entrance—the best from Maine to Mexico—the government agreed to pay the sum of \$5,250,000, and for the maintenance of the channel for 20 years the sum of \$100,000 per annum.

It may be asserted that every theory advanced by Capt. Eads, every statement made by him in relation to the channel which he should secure, has been fully verified by actual results. This project was declared chimerical by the experts of the government in published pamphlets, in written statements, and in verbal testimony before Congressional committees. These ideas were repeated in daily journals and in scientific and engineering periodicals. These opposing views were kept persistently before the public, hampering and jeopardizing the enterprise, and making it necessary to borrow money in order to carry it on at ruinous rates of interest. But Mr. Eads was never discouraged and never for a moment doubted the correctness of his theories. The Mississippi valley and the entire country is indebted to him for one of the greatest internal improvements the world has ever seen.

Latterly Mr. Eads has rendered very valuable service as a member of the Mississippi River Commission; which was created in 1879 by an act of Congress, and charged with the duty of examining the Mississippi and reporting a plan for its improvement. Mr. Eads has long contended that the true plan for deepening the channel is to correct the wide parts of the river by so contracting the high water banks at such places as to create a comparative uniformity of width throughout the alluvial districts. This he maintains will produce a uniformity of depth, and secure at least 20 ft. at low water from Cairo to the gulf. The report of the commission fully sustains Mr. Eads' views, and recommends the application of the principle advocated by him for the improvement of the river.

The last great proposition made by Mr. Eads is the construction of a ship railway across the Isthmus of Darien. He maintains that the railway is far more desirable than the level ship canal project of M. de Lesseps. By his railway Mr. Eads proposes to carry vessels of the greatest tonnage from ocean to ocean in a cradle supported by many wheels and carried on numerous rails. In support of this proposition he made an able address before a committee of the House of Representatives. We have said that audacity was a marked trait of Mr. Eads' engineering schemes; but in this last project of a ship railway, he appears to have surpassed himself. If the project shall ever be attempted, Mr. Eads, of all living engineers, is the man to accomplish it. That would be a lit climax to his splendid career.

In conclusion we will remark that the presence of Mr. Eads in California is full of interest. In 1878 the Legislature passed an act creating the office of State Engineer, and providing for the appointment of two consulting engineers, who were to advise with the State Engineer upon plans for the improvement of our rivers and kindred matters. Gen. Alexander and Col. Mendell were appointed consulting engineers; and upon the death of the former shortly afterwards the vacant place was, by the advice of those most deeply interested, tendered to Mr. Eads. Now that the State Engineer is assisted by such splendid talent, we may look for plans which will lead to the speedy opening of our rivers and the practical settlement of the irksome question of drainage. Our hope rests largely on the great engineer.

JAMES B. EADS, CALIFORNIA'S CONSULTING ENGINEER.

relieve the commerce of the river by the construction of a canal from its left bank, near Fort St. Philip, to Breton bay, by which the bars at the mouth of the river would be entirely avoided. Mr. Eads opposed this scheme vigorously in several pamphlets which he published. He contended that a canal with locks would be inadequate to meet the requirements of the immense commerce of this river. Instead of the canal he proposed the creation of a broad, deep, natural channel through the bar at the mouth of the river, by means of jetties or parallel dikes. Mr. Eads maintained that the effect of the construction of jetties would inevitably be to create such a channel, inasmuch as it would result in bringing the current of the river within narrow limits and greatly increase its velocity, and thus augment immensely the force required to carry far out into the deep water of the gulf the sedimentary matter with which the river is charged. Besides this, the increased velocity of the current would add largely to its scouring capacity. The interest in the vast project extended. In 1872 a commission, composed of seven U. S. engineers of distinction, was by act of Congress charged with the responsible duty of solving the problem; that is, to devise the best means to open the mouth of the Mississippi to commerce. In 1874 this commission recommended the construction of the canal already referred to. This report had its influence with Congress, for a committee of the House unanimously reported a bill to appropriate \$3,000,000 for the construction of the canal as recommended.

It was under these circumstances that Mr. Eads first went before Congress with his jetty project. His knowledge as an engineer, and his extensive knowledge of the Mississippi river, gave strength to the views he expressed. He called the attention of Congress to the

Mississippi. The end of this travel and investigation was, that six out of the seven members of the commission reported in favor of the application of the jetty system as proposed by Mr. Eads. There was, however, this difference between the commission and Mr. Eads: The latter proposed to construct jetties over the bar at the mouth of Southwest pass; the former recommended their construction at the mouth of South pass. Southwest pass was much larger and discharged a greater volume of water than South pass; there was deep water at its head, and it carried 14 ft. over the bar at its mouth. In the case of South pass there were two bars—one at its head with 14 ft. of water, and one at its mouth with not more than 8 ft. These facts show the reason why Mr. Eads preferred the larger pass. Convinced by the clear statements and able reasoning of Mr. Eads, the House committee reported a bill recommending Southwest pass, and it was passed. But when the bill came before the Senate it was amended by substituting South pass for the proposed improvement, and in this form it was passed and became law.

South pass having been forced upon Mr. Eads, he accepted the proposition, closed his contract with the government, and engaged in the vast work. In spite of the supreme difficulties which beset the prosecution of the work during a period of unusual financial depression, the dauntless engineer pressed on. His success was complete and brilliant. On the 8th of July, 1879, he had secured the maximum channel required by the terms of the law, namely: a channel 26 ft. deep, 200 ft. wide, and a central depth through its course of not less than 30 ft. When Mr. Eads began the work there were only 8 ft. of water on the bar, there are now 30 ft., admitting of the passage of the largest vessels afloat. Indeed, since the completion of the work the channel has been gradually growing

LIMESTONE LANDS—Lately a new question as to what constitutes mineral land under the act of Congress has been presented for the consideration and decision of the Land Office. It appears that a piece of land embraced in the area granted to the Southern Pacific railroad contained a valuable occurrence of limestone, which was taken possession of by a person who complied with all the forms required in entering it under the mineral land law. The case was appealed to the General Land Office. The commissioner has decided that it cannot be held as mineral land within the meaning of the law. If the claimant's construction of the law were allowed, then not only limestone, but also sandstone, different kinds of clay and gravels, might be entered under the law, and the title to half of the homesteads in the west would be clouded. The commissioner held that only those lands which were more valuable for the production of the precious metal than for any other purpose could be considered mineral land in the meaning of the law, while the body of land in question, which yielded only limestone, could not be so regarded. If the decision of the commissioner has been correctly reported by the telegraph, it would appear to have been based upon a rather narrow and strained construction of the law, so far, at least, as it concerns the relative value of lands. For example, a tract of land might contain veins or deposits of gold or silver, which might under certain probable conditions be more valuable for some other purpose than the production of either gold or silver; would that state of facts shut it out from entry under the mineral law? We think it would not. In other respects, the decision of the commissioner, excluding limestone, and all other rocks and clays which have a distinctive economic value, appears to be fairly in accord both with the spirit and letter of the law.

One Hundred Years Under Water.

Mr. J. W. Dutton, the constructing engineer of the celebrated Dufferin Palace in Quebec, recently presented a journalist with a cane and a pencil holder made of the wood of the vessel *L'Original*, which was sunk before Quebec in this year 1756. In a letter accompanying his gifts Mr Dutton says:

L'Original was built just below the Citadel, scarcely a quarter of a mile from where Montgomery fell 19 years later. For those days she was a large vessel, but in this age a 1,000-ton vessel is not much to tell of. She was built of oak timber, which must have been brought from France; as none of the Western oak forests had been cut into, it being impossible then to bring the timber down. The vessel was built of the best timber and iron, but she was fated never to do much execution for her country, as shortly after being launched she was sunk, just opposite where she was built.

There she lay until last summer, when she was raised and towed to shore. She sank in September, 1756, so that she had lain under the waters of the St. Lawrence about 123 years. In spite of her long immersion, when they first attempted to raise her it was found impossible, on account of her being sunk in the mud, and it was equally impossible to tear her to pieces as the oak was as solid as on the day she went down. The only thing that was gone was the iron, in those places where it had been exposed, and this had completely rusted away. After several vain attempts to stir her, a diver was sent down, who fired a heavy charge of dynamite under her. This broke her up somewhat, but it was only after many explosions and two years' hard work, that she was finally got rid of.

The wood was eagerly sought for, and now it is almost an impossibility to get a piece of it large enough to make anything of any value. The frigate was the last relic of the old French government, having been built under the superintendence of the Intendant Bigot. She lay in 90 ft. of water, and while she has been there many are the changes that Quebec has seen—as well in manners and customs as in men. When she was removed there were found to be over 100 anchors of all sizes and many hundred fathoms of chain entangled with her. These were, of course, raised, and in some instances claimed, but most of them were sold by the government to satisfy expenses.—*Iron Age*.

AN UNSCIENTIFIC HAT.—Miss Kate Field, discussing the fitness of hats for their purpose, has this to say of the tyranny of the "stove-pipe" in England: It is as much as a man's life is worth—in society—to wear aught but the regulation stove-pipe. There may be M. P.'s who dare to face the Speaker with billy-cock or soft-felt hat in hand, but I doubt it. The only man I ever heard of equal to such an amount of bravery is Joseph Cowen, the member for Newcastle and owner of the radical *Newcastle Chronicle*. He at all times has the courage of his opinions. Whether people agree with him or not, all admire his pluck, a pluck backed by brains. Joseph Cowen would be an orator were it not for a Northumberland burr which prevents him from being fully understood. "Very elegant speaker is Mr. Cowen," once exclaimed Lord Beaconsfield; "What a pity no one knows what he is talking about!" Cowen the Radical, wears a slouch hat, but I should no more expect to see Sir William Harcourt in such a covering than I should expect to see elephants in satin gowns. No one in England who is not a rough or a genius can afford to wear a slouch hat. Alfred Tennyson is rarely seen in anything else. Wilkie Collins and Charles Reade defy public opinion, but I firmly believe that even these men would wear stove-pipes were they daily subjected to the insinuating respectability of the House of Commons. Stove-pipes permeate the atmosphere and play an important part in the legislation. So greatly do they tyrannize over the British male that even Eton boys in jackets are swallowed up by them. Talk about woman's blind devotion to fashion! Did ever woman cling as fondly to crinoline as man clings to his stove-pipe? Never!

A NEEDED REFORM.—The manner of furnishing meals to immigrants while on the way to their Western destinations, says the *New York Times*, having caused much inconvenience and suffering to this class of travelers, the New York, Lake Erie & Western Railroad Company has determined to take the matter under its own management, so far as the immigrants traveling by its route are concerned. The right of furnishing meals has heretofore been let to restaurant keepers. General passenger agent Abbott recently devised a new arrangement for Erie immigrants, which was first tried at Buffalo a few days since. It resulted in such great satisfaction and convenience to the travelers that it will be introduced wherever refreshment stops are made. The immigrants are now allowed the entire freedom of the inclosures at the Buffalo depot, and all outsiders are prohibited from interfering with them in any way. The company furnishes them wheat bread, rye bread, Swedish bread, pies, cheese, bologna sausage, milk, coffee, cigars and tobacco, all of the best quality, at merely the cost of the articles. The immigrants are given comfortable places and abundant time to take their meals in.

A MONSTROSITY.—There is on exhibition at the store-rooms formerly occupied by Jake Heusser, a monstrosity which beats anything that has ever come to this city. It is doubtful indeed, if its like is to be found, search the world over, and the strangest feature of the whole affair is that the curiosity is living. On entering the room reclining on a bed is a mammoth head. That is about all there is to, this strange existence. Its body is small and its limbs can be circled with a band. Its total weight is 70 lbs, its head weighing 45 of them. This monstrosity was born in Worth county, Missouri, on the 26th day of January, 1855, and is now 25 years old, four ft. two inches high, and weighs 70 lbs. His head measures 36 inches around. The organs of speech and hearing are said to be perfect, though this is doubtful. Though uneducated he easily memorizes anything he hears. He also has a splendid musical talent and can sing anything after having once heard it. His head was unusually large when born, and grew to its present size by the time it was two years old, during which time he worried, fretted and cried day and night. Although he has been confined to his bed his whole life, unable to walk, roll over, move his head, or help himself in the least, he has always enjoyed perfect health, never missing a meal; being deprived of exercise, as his situation necessarily places him, he enjoys a good appetite and eats heartily. His limbs are unusually small, which he cannot move except his left hand. He is ever cheerful, ready and willing to answer questions. The head is pear-shaped and repulsive looking.—*Salt Lake Tribune*.

SPECIAL PERILS OF THE WORKSHOP.—Public feeling has been a good deal excited in West Yorkshire by the recent inquiry into the death of a wool-sorter in Bradford, who had died of what is known as wool-sorters' disease, apparently a species of blood-poisoning, caused by the entrance through the lungs into the circulation of a small organism, originating either in the animal which produced the fleece, or during its decomposition, the organisms being sometimes of an animal and sometimes of a vegetable nature. The medical attendant of the deceased said he had seen many cases of this peculiar malady, and it appears that it may be prevented by keeping the fleeces for at least 12 hours in water heated up to 120 deg. Notwithstanding the cause of this complaint is so well known, and the remedy also, it was stated in court that wool known to be dangerous has been placed in the sorters' hands after having been merely rinsed in cold water, and it was deposed that many of these men had been attacked by the disease and some had died in consequence. The jury made a presentment to the effect that proper regulations on the subject should be made and enforced, but this is a matter which properly-minded employers should look to without the necessity of being driven to it by legal enactment. There is a great and unnecessary waste of life and destruction of health in London in this way from want of thought on the part of manufacturers, often in industries in which the workers are very poorly paid.

A RAILWAY ACROSS SAHARA.—To the objections raised by certain explorers, that a railway across the Sahara would be buried from time to time in sand, and that the savage inhabitants of Africa would interfere with the construction and operation of the line, even if it were desirable as a commercial enterprise, its French promoters reply that the inconvenience from sand can be but slight compared with that from snow on many of the American railroads and if it should prove serious, the same mode of protection by sheds can be employed against simoons which is found so useful against winter storms in the Rocky mountains. As to the natives, they will soon learn that passenger trains are not sent to provide them with "meat," and annoyance from them will cease. All this seems reasonable enough, and there is no question that Africa is on the brink of a vast and rapid development. Already the route which Stanley pursued so painfully is practically open to travel, many others are being established, and if we are not mistaken railway supplies have recently been shipped to Zanzibar for use upon the continent. We confess to personal disappointment at seeing the prospect of Saharan sea fade away. To say nothing of the amelioration which it was expected to work in the summer climate of Southern Europe, the thought of having to traverse the desert by land instead of water, even in a railway car, has little that is attractive.—*American Architect*.

FIRE ON A RAILWAY TRAIN.—The Battle Mountain (Nev.) *Register*, of July 31st, says that on the down trip from Austin last Tuesday, when the train was a short distance this side of Mound Springs, it was discovered that one of the box cars containing wool was on fire. An effort was made to put out the fire, but as it had gained a good start before being seen, all attempts to subdue it were futile, and the car was run on to the side track at Bailey's station and left to burn. The wool belonged to P. Duffy, and was being shipped to this place for sale. It was valued at about \$1,600, and was a total loss. The car cost \$800, and will be almost a total loss to the company, as nothing remains except the charred wheels, so that the Nevada Central's loss will foot up nearly \$2,400 on this accident. It is supposed to have caught from a spark from the locomotive.

AN ANTIQUATED CITY.—A correspondent of the *Boston Traveller* makes this interesting mention of Cordova, once the capital city of the Mahomedan empire in Spain, and at one time the favorite shelter of learning when Europe was sunk in darkness and barbarism, is located on the river Guadalquivir, and has a population of 43,000. The wall surrounding the old Moorish town is flanked with square, round and octagonal towers; however ancient, it is all kept in excellent repair. Seldom is a city found having a finer location, encompassed by a magnificent plain, with lofty blue mountains in the distance, and at one side, not many miles away, are luxuriant hills, whose precipitous sides are dotted with abbeys and monasteries. Their massive white walls and domes reflect imposingly in the sun, as seen from the promenades lined with magnolias, that are outside the city walls. No other city in Spain, to my mind, presents so singularly decayed an appearance as Cordova. There is a charming quietude in wandering through its narrow, winding and clean streets, mostly paved with small round stones. But few carriages are in the city, which evidently from the first was not intended for such, most of the streets being too narrow to admit them. Saddled horses and donkeys can, however, pass almost anywhere, but only occasionally are they seen in other than the market places and broader thoroughfares near the limits of the town. The houses are two stories in height, of stone or brick, and mostly white; some are painted blue or yellow, all having small inner courts with neat little fountains in the center. These fountains are of different designs, with constantly-playing water, and present a most cheering appearance, surrounded as they are by small orange and lemon trees, and seen by the passers-by through the iron-latticed doors and windows.

NATURE'S SILVER PLATING.—Lately a reporter of the *Gold Hill News* was shown some very peculiar specimens from the Lord of Lorne mine in the American Flat section. They were from the foot and hanging walls of the ledge, and on the sides next to the vein were covered with a thin film or natural plating of pure silver, as smooth as glass. The vein itself is narrow, and is being prospected by means of a tunnel running south. Mr. McDougal, the Superintendent, says this peculiar feature of the enclosing walls is observable throughout so far as the tunnel has followed the ledge. The ore of the vein itself is of a soft, easily-worked nature, showing considerable chloride as well as sulphurets, yet not giving very high assays. The filmy deposit of silver on the walls was evidently condensed and forcibly deposited there under immense pressure, as it has a smooth, burnished appearance, with strong, vertical erosions. It is quite a curiosity.

COAL OIL MONOPOLY.—We have often referred to the virtual monopoly which the Standard Oil Company has of the refining of petroleum. Several years ago they succeeded in buying up or leasing nearly all of the oil refineries in the country, and within the past week they have bought two of those remaining, leaving but one at Pittsburg out of some 30; and of all the refineries in western Pennsylvania, there are but four others in the oil region that are not controlled by the Standard. It is also reported that they have "fixed" the New York independent refineries and the Tide-water Pipe Line, and that they now propose to put crude oil up from \$1 a barrel—where it has been for some time—to \$3. Whether this latter is true or not, there is a firmness in the oil market that cannot be explained on any reasonable basis of demand and supply.—*Iron Age*.

A MINE has been discovered somewhere near the head of White river, a distance of about thirty-five miles from Delano, Kern county; out of which a sufficient quantity of gold and silver ore has been extracted to give a good general idea of its merits, the result being as follows: Gold, per ton, \$5; silver, \$235, and copper, 7½%. Besides this, the vein is three ft. in breadth, runs north and south, and pitches at an angle of 45 degrees west.

ST. DAVID'S,

A FIRST-CLASS LODGING HOUSE.
CONTAINS 113 ROOMS.
715 Howard St., near Third, San Francisco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms. Gas and running water in each room. The floors are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 8 A. M. to 10 P. M. Hot and cold water in a large parlour and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from \$2.50 upwards.

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

MONEY TO LOAN!

\$500,000

To loan, in one sum or in amounts to suit on Wheat Lands, Wheat in Warehouses, and other good collaterals at current rates of interest.

Savings Bank Books.

The highest price paid for balances in The Savings and Loan (Clay St.), Odd Fellows', Masonic, French, Farmers and Mechanics', by

MINING ENGINEER,
Room 75, 115 Broadway, New York.

Agent for PADDOK'S Ore Dressing Machinery.
Mining Machinery supplied.

San Francisco Cordage Factory.

Established 1856.
Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarrad Manila Rope, Hay Rope, Whale Line, etc., etc.
Extra sizes and lengths made to order on short notice.
TUBBS & CO.,
611 and 613 Front Street, San Francisco

INCERSOLL ECLIPSE ROCK DRILLS.

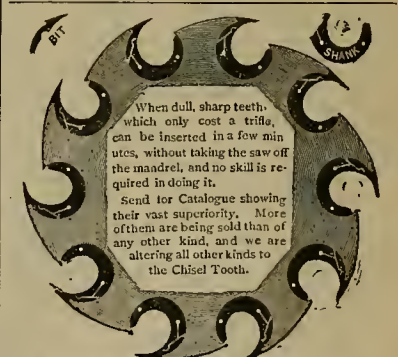

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is hoisted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,
49 Fremont St., S. F.

Stearns' M'fg Co's Unequaled Pacific
SAW MILL MACHINERY.
Automatic Slide Valve, Universal Automatic Corliss and Cheap Hoisting ENGINES and BOILERS.

TATUM & BOWEN,
329 Market Street, 3 Fremont Street

OXYGEN.

What is it? Everybody knows it is as essential to life as food itself. Yet when people are ill for the very want of revitalization through respiration, they dose themselves with drugs and hitters to the effect of demoralization! All Invalids should read Drs. STARKEY & PALEN'S (Phila.) *Treatise on Oxygen*, which is sent free to all who may ask for it. The subject is worthy of investigation. References to physicians in San Francisco, who use and prescribe Compound Oxygen in practice. As prepared for home use (conveniently sent to any address) it may be obtained of H. E. MATHEWS, 606 Montgomery street, S. F., upon the same terms as furnished by Drs. Starkey & Palen, Philadelphia, Penn. Complete instructions with each package.

Metallurgy and Ores.**Nevada Metallurgical Works,**

No. 23 STEVENSON STREET.
Near First and Market Streets

Ores worked by any process.
Ores sampled.
ASSAYING in all its branches.
Analysis of Ores, Minerals, Waters, etc.
WORKING TESTS MADE.

Plans furnished for the most suitable process for working Ores.

Special attention paid to Examinations of Mines; plans and reports furnished.

E. HUEN,
C. A. LUCKHARDT,
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS.

Mine and Mill Supplies,

CHEMICAL APPARATUS AND CHEMICALS, DRUGGISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17 California St., San Francisco.

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Muffles, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co. of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.

Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

W. BRUCKNER'S**ROASTING FURNACE**

AND

Ore Pulverizers.

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.

The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps. Furnished also in sections for packing.

For circulars and prices apply to

W. BRUCKNER,
Mining Engineer,
328 Montgomery St., room 16

Machinery.**GOLD AND SILVER****Grinding and Amalgamating MACHINERY.**

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

**SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.**

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,550.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

MOREY & SPERRY,

No. 145 Broadway, - - NEW YORK.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY Saw User.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1875.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, sash, mill, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, sawing, gumming, filing, etc., tables of gauges, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed, and owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AMERICAN MACHINE AND MODEL WORKS.

Experimental and Fine Special Machinery, Planing, Gear Cutting, Patterns, Models for Inventors, etc. Printing Press and General Machine Repairing. Punches, Dies, Taps, Reamers, etc., made and repaired.

I. A. HEALD, Proprietor.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions rendered upon patent cases in litigation, for the benefit of our readers:

COMMISSIONER'S DECISIONS.

Manufacturer of Oil-cakes.

Ex parte McDougall. Appeal from Primary Examiner—Decided, June 14, 1880.

1. The rule that several distinct inventions cannot be included in a single application is applicable whether such inventions be improvements in processes or machinery, and the mere circumstance that several processes pertain to the same subject-matter, will no more warrant their inclusion in a single application than will the bare fact that two machines are in the same class of invention warrant the issue of one patent for the two.

2. Although each of the several "acts" of the "series of acts," constituting a process may be capable of performing separately its own peculiar function, and may be used independently of the others, yet if they all contribute in producing the final result they must be joined in a single application, and a claim may be made to the entire process, and separate claims can also be made to the sub-processes, which go to make up the same.

3. When one has discovered that a desired result can be attained by a process consisting of a series of steps, and that certain of the steps in such process can be replaced by others which will operate in an equivalent manner, a broad or generic claim can be made including all the modifications, and a more limited or specific claim can be made to any one of the modifications.

4. Where in several processes the order in which the several steps follow each is different, as are also the final results attained, the processes cannot be said to be modifications each of the other.

5. Alternative claims and claims for modifications condemned. The mere fact that courts, in order to save a patent, have sustained such claims is no warrant for the Office to shrink its duty in requiring that the claims shall be framed in the clearest and best form, and shall not embrace distinct inventions.

Decision of the Examiner confirmed.

ACTING COMMISSIONER'S DECISIONS.

Improvement in Refrigerating Cars.

Booth vs. Lyman et al. Decided July 2, 1880.—Appeal from Examiner of Inferences. Stockbridge, Acting Commissioner.

1. The *prima facie* date of invention of a patentee in an interference is the record date of the filing of the application upon which the patent was granted, and the mere allegation that certain records of this Office establish an earlier date cannot, without some connecting link in the application, give a different record date.

2. Such records, when properly introduced in evidence during the period assigned for taking testimony, may well be relied upon for what they are worth; but the adverse parties are clearly entitled to an opportunity to introduce evidence to rebut the same.

* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

HEATING FURNACE.—John L. Trefren, Santa Cruz, Cal. Patented August 3, 1880. No. 230,837. This invention relates to certain improvements in air-heating furnaces, such as are used for furnishing heat to churches, halls or private dwellings. The fire-box, or box stove, is made of corrugated iron castings, which gives it a great heat-generating power, and it is inclosed in a heating chamber; outside of this chamber is another chamber, and outside of this again are the outer or inclosing walls, forming another chamber. Each of these chambers opens into a central one above. When only

one or two rooms are to be heated, the supply of air to the outer chamber is cut off, and it then answers as a sort of jacket to the central chamber and prevents radiation of heat. A heater constructed in this manner is very economical in fuel, and a comparatively short time only is required to generate heat.

SHEEP SHEARS.—David E. McKee, Potter Valley, Mendocino county, Cal. Patented August 3, 1880. No. 230,712. This invention consists in interposing between the hinged handles a supplemental hand-lever hinged to one side of the handle, and having a swinging link or arm hinged to the other side of the handle, a spring being provided to throw the hinged handles open. What is known as the "hand-hold" is not so wide as when both sides of the handle have to be grasped, and the work of using the shears is materially reduced.

EXPLODER FOR BLASTING-CHARGES.—W. S. Rosecrans, S. F. Patented Aug. 3, 1880. No. 230,820. This invention consists of an exploder formed of a tube of metal capable of holding the enclosed powder, when ignited, under considerable pressure, in combination with a powder filling incapable of explosion except when ignited within a case capable of holding it under pressure; and, second, it consists in the peculiar manner of holding the fuse within the tube and the exploding powder under pressure.

STREET CAR.—Walter N. Hawley, S. F. Patented Aug. 3, 1880. No. 230,774. This car consists of three longitudinal compartments, the outer ones of which may be sub-divided into as many sub-compartments as may be desired by transverse partitions, while the central compartment forms a narrow continuous passage from end to end of the car. The side compartments are closed in and provided with windows, and each side compartment can have a central door-opening for ingress and egress.

PICTURE-HOOK.—John T. Haveland, S. F. Patented August 3, 1880. No. 230,701. This invention relates to certain improvements in that class of devices known as "picture-hooks" or "hangers," and it consists in the combination with a curved plate, hook or hanger, on a roller or pulley, over which the supporting-cord passes, and which, by turning freely upon its axis, allows the picture to be adjusted to hang freely.

The Opening Address of P. B. Cornwall, President of the Mechanics' Institute.

The opening address of the Fifteenth Industrial Exhibition of the Mechanics' Institute, was delivered by Mr. Cornwall, President of the Institute. It was well received by the large and appreciative audience. Mr. Cornwall spoke as follows:

Custom has served to make it necessary for the President of the Mechanics' Institute to deliver a brief inaugural address at the opening of each industrial exhibition held under the auspices of the Institute. We have met here to-day to conduct the preliminary exercises incident to the opening of our fifteenth exhibition at the Pavilion on Eighth, Market and Mission streets. The first meeting of the mechanics of San Francisco for the purpose of organizing the association now known as the Mechanics' Institute, was held at the office of the Tax Collector in the City Hall, on the evening of the 11th day of December, 1854. G. K. Givens presided. The committee appointed for the purpose reported on the 6th day of March, 1855, a constitution, which was adopted; and on the 29th day of March, 1855, a permanent organization was effected, with Benjamin Haywood as President. On the 24th day of April, 1855, the proper certificate was filed in the office of the County Clerk, by which the Institute became a body corporate under the laws of the State.

At the end of the first year of the existence of the Institute, March 5, 1856, there had been expended \$1,106.86, and a balance of \$21.49 remained in the treasury. Two hundred and eighty-two members were enrolled, but only 92 had paid their quarterly dues. The library consisted of 457 volumes. During the succeeding 10 years the Institute struggled on bravely, occasionally holding a fair, with varying success, but always making valuable additions to its library. From 1866 to the present time the Institute has steadily increased the size and improved the character of the library, and in other ways enlarged its ability to do good. At this time it is possessed of unincumbered property valued at about \$257,000, with no indebtedness except about \$3,000 unpaid taxes. The library contains 29,000 volumes, of which 14,000 compose our reference library, which is undoubtedly the most complete and valuable collection of scientific works on this coast. It is but just for me to say here, that for this remarkable progress, and for the successful establishment of the Institute on a firm and secure basis, San Francisco is more indebted to the intelligent and unselfish labors of Andrew S. Hallidee, who was its President and leading spirit for many years, than any other person.

Among the things now in contemplation by the patrons and friends of the Institute to increase its usefulness, is the establishment of an apprentices' department, where regular and frequent meetings of apprentices may be had for the purpose of investigation and debate upon mechanical and other subjects, and the institution of a system of lectures and classes for technical education, where skilled workmen and learned teachers may explain the methods by which the hard things of life are made easy, the confused clear and the doubtful certain. By these and kindred means, the increasing thousands of idle youth growing up in this city, many of whom, because of idleness, are drifting into vicious ways, may be diverted into channels of intelligent mechanical industry, and grow into useful and respected citizens, with happy homes, thus adding to the aggregate wealth and prosperity of the country. It has been said by some who object to this course, that there is no room for more mechanical labor here, that the market is over-stocked; and that we cannot successfully compete with mechanical products shipped from the eastern side of the continent, because labor there is cheaper. I have sometimes thought that this difficulty lay more in the indifferent way in which many of our manufactories are conducted, and in the absence of those close and systematic economies, which are essential to success in all manufacturing enterprises; and I have observed, that in most instances where by patient, intelligent labor and skill, the highest excellence has been achieved by the San Francisco mechanic, he has driven out of the market the kindred wares of Eastern or foreign product. It is true that, owing to our comparatively isolated position, the mechanics of San Francisco have heretofore been practically limited to California, Oregon and Nevada for a market in which to compete for the sale of their products, but by the building of the Southern Pacific railroad into Arizona the field has been greatly enlarged, and the proposed extension of the Southern Pacific and connecting roads into and through Mexico will soon open up a vast and productive field for enterprise, into which the industrious mechanics and resolute manufacturers of San Francisco can send their machines and wares for successful competition and sale, if they are so made and finished as to do credit to their craft. There is in the minds of many persons a prejudice against their sons being apprenticed to and educated as mechanics. I believe it is all wrong. What has mechanism done that such prejudices live? Without the mechanic the world would never have emerged from barbarism. Without the mechanic no ship would have been built in which the hold mariner could sail and discover America. The ponderous engines that drive the steamship through trackless oceans; the finest lace that is woven for the infant's couch; the houses we live in; the books we read; the clothes we wear; the table at which we sit; the plates from which we eat; this beautiful temple in which we are gathered, and all of our comfortable and ornamental surroundings here and at our homes are the products of intelligent mechanism. I believe that there is a greater proportion of useful men with happy homes among mechanics than in any other class of life, not excepting farmers.

A thorough education in any branch of mechanism does not prevent the possessor thereof from entering any of the other walks of life which may afterward seem useful and pleasant to him, but is an additional qualification for success in almost any private or public place—happily in this country there is no place so high that the humblest child or man may not aspire to it, and with studious habits, pure life and resolute determination, he may reasonably hope to succeed in writing his name high on the roll of fame. The history of our country is full of such achievements. I need go no farther for an example than point to the trained and skilled mechanic who is to deliver the oration to you to-day, who rose step by step from the printer's case to the Senate of the United States, where he was the peer of any man in that greatest of all deliberative bodies. Let us not then be afraid to educate our sons to be mechanics, but let us rather take care that the rising race of manufacturers grow up better skilled in mechanics, better repented for quality of materials, and more discerning in matters of taste. Then shall we do well for our fellow men and help to continue and increase national prosperity.

MANUFACTURING IN RUSSIA.—A recent report from the German Consul-General at Moscow, gives some information concerning the manufacturing industries of Russia. There are about 15,000 factories in the empire, producing goods to the value of 500,000,000 roubles (\$325,000,000) a year. At Moscow the wholesale trade is almost entirely in the hands of Germans—that is, either Russian subjects of German origin, or subjects of the German empire. Among the manufacturers, on the other hand, the Russian element predominates. Imported goods, which formerly came chiefly from France, are now almost entirely of German production; year by year the French imports are diminishing, while the German imports are increasing.

STURDY STOCK.—Senator Hamlin, of Maine, is thus described: He has never known sickness, and has been most careful and attentive to his public duties, of whatever character, of any man in the country. He never wore a piece of flannel, or underclothing of any description, a pair of gloves, or an overcoat. Even in our coldest weather, Mr. Hamlin, even at his advanced age, plods along, dressed in the coldest of costumes—the old-fashioned swallow-tailed coat—without wraps of any kind, while his fellows are almost frozen to death beneath his overcoats and the heaviest of underclothing. His power of endurance is wonderful, and his capacity for work great.

News in Brief.

OVER 400,000 Texas cattle have been driven into Kansas this season.

BERMUDA grass is valuable to bind ditch banks and levees against the force of a current. A PLUMAS hunter shot nine deer during the past month, one of them weighing 170 pounds. In the English census the champion name is "Hostiliana Ophigenia Maria Hyphile Wage."

ON a recent trip of one of the White Star steamers \$400 were collected for the Sailors' Orphan Home.

WILD strawberries, swet, luscious and plentiful, cover many acres of the meadows near Donner lake.

RUSSIA has ordered the construction of tan clippers, five of which are to be built in the United States.

THE couple arrested as the notorious Benders are pronounced by the people of Kansas to be frauds and beats.

ONE of the features of a voyage on the French steamers is the gratuitous distribution of very good table claret.

WHEN a school of black fish appears off a Cape Cod village, all rush to the capture, even though at church.

NEW YORK is treated to a greater variety of offensive smells than any other settlement on the face of the globe.

BERLIN has now a club composed of the English and American residents of the city. It is said to be successful.

MR. FROUDE was among those who strongly opposed the Westminster monument to Louis Napoleon from the first.

MANY of the so-called club-bouses at the fashionable summer resorts are no more and no less than gambling-houses.

By a railroad accident near Waverly, O., August 7th, David Dungan was killed and 15 persons were injured.

OF THE eight steamers now in the service of the American line of Philadelphia, four are English built and named.

THE hogs in the vicinity of Angels, Calaveras county, are attacked by a throat disease, which is proving very fatal.

MORE British troops are ordered to Ireland, in view of possible disturbances growing out of the enforcement of the land laws.

REV. W. H. H. (ADRIAN) MURRAY is reported to be engaged in a large and profitable commission business in Liverpool.

Boston Methodist preachers have petitioned the municipal authorities to abandon free concerts in the public parks on Sunday.

J. McDONALD GARDENER, a Connecticut teacher, is going to Japan as professor of English literature in a high school at Tokio.

THE British have 40,000 troops in Afghanistan. The recent battle between Burrows and Ayoub Khan was fought near Hyderabad.

ONE result of the elections in Mexico is that not a deputy who voted to delay the passage of railroad bills has been returned to his seat.

A STANISLAUS county thresher recently threshed 9,016 bushels of wheat in three days and three hours, with the usual stoppages.

THE increase of alleged French flats in New York is remarkable. Several dozen are now being erected in the upper part of the city.

THE family of Phelim Toole, the fireman who was recently killed in St. Louis, have received over \$7,000 by subscription of the citizens.

THE first woman ever ordained to the Christian ministry in Europe is Carolue A. Soule, who is a Universalist preacher in Scotland.

MR. BRETE HARTE, our Consul at Glasgow, has become a regular contributor to the *St. James Gazette*, the new London newspaper.

NATURAL caverns of large size, one, at least, being 600 ft. long, have been discovered at West Hartree, near Wells, Somersetshire, England.

A CUBAN family at one of the Saratoga hotels has a weekly board bill of \$450. This is for 6 adults, 3 children, 2 maids, coachman and valet.

A PETITION was recently presented to Parliament from the British Medical Association, signed by 7,000 medical men, against vaccination.

THE British have received another good drubbing in Afghanistan, losing ten men and the greater part of their baggage, animals and treasure.

IT is told of a monkey who had suffered from a toothache for several days that he tied a string to the offending tooth and pulled it out with a jerk.

A GERMAN newspaper claims to have discovered that Goethe was descended from a Bavarian family, bearing the name of Gotze, and living in 1449 at Henstren.

THE American and English Bible Revision Committee are said to agree in 99 cases out of 100. Work on the New Testament will be finished in September.

LEWISTON has \$590,070 invested in 78 factories, outside of cotton and woolen, which pay 1,256 persons \$296,277 a year for making \$1,263,968 of products.

A BRAKEMAN on an Indiana freight train, who permitted a man to ride with him on the top of a car, undertook to collect fare, and shot the passenger for refusing to pay.

THE Countess of Cork recently gave a "rose hall" in London, the house being filled with roses, and all the guests adorned with roses of all imaginable sizes and shades.

TWO hundred Cherokees are assembled at Fort Gibson ready to attack the Creeks unless the latter surrender 13 Creek negroes who attacked a party of Cherokees and killed two of their number.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Boltho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

HALL'S VEGETABLE SICILIAN HAIR RENOWER is a scientific combination of some of the most powerful restorative agents in the vegetable kingdom. It restores gray hair to its original color. It makes the scalp white and clean. It cures dandruff and humors, and falling out of the hair. It furnishes the nutritive principle by which the hair is nourished and supported. It makes the hair moist, soft and glossy, and is unsurpassed as a hair dressing. It is the most economical preparation ever offered to the public, as its effects remain a long time, making only an occasional application necessary. It is recommended and used by eminent medical men, and officially endorsed by the State Assayer of Massachusetts. The popularity of Hall's Hair Renower has increased with the test of many years, both in this country and in foreign lands, and it is now known and used in all the civilized countries of the world.

FOR SALE BY ALL DEALERS.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

INVENTORS, and others interested, will receive DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY Circular free on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

J. G. COLMERNEL is requested to report to this office from Humboldt Co.

Chew Jackson's Best Sweet Navy Tobacco.

NEW UPRIGHT WILCOX ENGINE.

1-inch Cylinder, 6-inch Stroke. About 8-Horse Power. Will raise 3,000 gallons per hour. Was used to dig the well at Chronicle office. Never used otherwise, and is in perfect order.

PRICE, \$300.

Mr. Wilcox sold similar engines at \$800 each. I have taken this engine as an attorney fee, and will sell it for this price and WARRANT it. Address

MANUEL EYRE,

Law Office, No. 636 Clay St., room 25, S. F.

Some fine sunny offices (next to the PRESS office), to rent (at very reasonable rates), by Dewey & Co., at 202 Sansome street, corner of Pine,

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company,
SAN FRANCISCO, AUGUST 2d, 1880.

At a meeting of the Board of Directors of the above-named Company, held this day, Dividend No. 18, of Seventy-Five Cents (75c) per share was declared, payable on THURSDAY, August 12, 1880, at the office in this city, or at the Agency of the Nevada Bank of San Francisco, in New York. WM. WILLIS, Secretary.

DIVIDEND NOTICE.

OFFICE OF THE

Consolidated Virginia Mining Company,
Nevada Block, Room 26, S. F., August 7, 1880.

At a meeting of the Board of Directors of the Consolidated Virginia Mining Co., held this day, a Dividend (No. 53) of Fifty (50) Cents per share, was declared, payable on Monday, August 16, 1880. Transfer books closed until the 17th, inst. A. W. HAVENS, Sec'y.

Gover Mining and Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the Eleventh day of August, 1880, an assessment (No. 49) of 20 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Thirtieth day of September, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the Eleventh day of October, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. O. WILSON, Secretary.
Office—402 Front street, room 8, San Francisco, California.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

SAN FRANCISCO, SATURDAY, AUGUST 21, 1880.

VOLUME XLII
Number 8.

The Mears Chlorination Process.

This new process, the invention of Doctor Mears, is receiving large and deserved attention from practical mining men; for it presents more grounds for confidence than is usual with new processes, even after good results on a small scale have been obtained. As the invention has received some personal examination from the *Engineering and Mining Journal*, we give a summary of its account for the benefit of those who have applied to us for information respecting the process, as well as for the general reader. It is conceded that Dr. Mears has devised a thorough and rapid method of extracting metals, gold especially, from their ores by chlorine gas under pressure. The expense is moderate, and it can be applied to many good mines with advantage to the production in saving more of the fine gold than is possible by amalgamation, and probably in reducing the cost of treatment by the Plattner process.

The editor of the *Journal* thinks Dr. Mears is justified in claiming that he can treat charges of ore in less than one-fifth of the time required by the old process. The cost of treatment by the Mears process is given at from \$2 down to 50 cents per ton, according to the local conditions; and it is believed that in most cases the cost will be below the higher figures. The process is now under development in a sensible way at mines. Its owners are men of character and business experience and capital enough to push the process in a proper manner where it will be of use in legitimate mining. These gentlemen place at the disposal of responsible parties interested in testing their ore on a small or a large scale, an apparatus in Philadelphia, in which 100 pounds may be treated at a charge, or a mill in North Carolina, where 10 or 100 tons can be treated, "so that there need be no taking it on faith, works being so accessible." Already the process has been purchased for a number of properties both East and West.

The process is briefly described as follows: "It is an improvement on the old Plattner process of treating ores by chlorine gas, and consists in hastening the combination of chlorine and metal by applying a concentrated solution of chlorine under pressure. Charges of a ton each are treated in revolving, air-tight, lead-lined iron cylinders, from one to two hundred gallons of water being present with each charge. Fine gold is dissolved almost instantly. If properly roasted and pulverized, successful work is done in as short a time as thirty minutes; all calculations are at present, however, based on from one to two hours for each charge. When chlorination is complete, the fluid mud is poured into a filter, thence the chloride of gold in solution runs to a precipitating tank, where it is thrown down by sulphate of iron. Since chloride of silver is not soluble in water, it must be subsequently leached out by one of the well-known methods."

COMSTOCK AIR GALLERIES.—The main north drift starting from the Ophir incline, at the 2500 level, has now passed through the Ophir and Mexican claims and has just reached the Union Consolidated ground, which it has penetrated a distance of 7 ft. The distance across the Union Consolidated ground is 575 ft. but to connect with the Union shaft the drift will not have so far to go by about 150 ft., therefore it will not be long before there will be a grand air gallery on the 2500 level all the way from the Sierra Nevada to the Ophir, and eventually to the C. and C. shaft, and probably southward into the middle mines. It is these great galleries that cool the lower levels of the mines. All the air that could be blown into them, or in any way forced in by mechanical means, would amount to nothing. But by the plan of running these galleries, and connecting them at proper intervals with the vertical shafts, great volumes of surface air pass down to the lowest levels at one point and, traversing the galleries and other openings, come to the surface at another. The larger the openings the larger the volume of air, and the cost for ventilation is nothing after the openings are made; also, the deeper the workings the stronger is the rush of the current of air. —*Enterprise*.

Remarkable Performances Under Water.

A recent number of the London *Times* contains an account, which we summarize, of some remarkable performances under water of Fleuss, the diver, and the patents of the diving apparatus. He appeared at the Royal Aquarium, in the large tank built for the whale and used by the seals, and remained under water two hours and seven minutes. He claims to be able to stay under water for five hours without an air tube or any other connection with the surface, and this circumstance gives him larger freedom of action than is possessed by other divers. For example, he can lie down and bend his body in any position without fear of being lifted up or floated. He possesses the advantages of being able to move independently instead of being rooted to one spot. The diver presents a curious appearance under water, with goggle eyes in his burnished helmet, a strong water-tight dress, and water boots. Spectators amuse themselves by throwing pence for him to pick up. He sharpens his pencil under water, and

THE COLEMAN TAPPET FOR QUARTZ MILLS.

writes answers to messages sent to him on cardboard. At Ryde he walked for a quarter of a mile under the sea; and at Brighton he went down in five fathoms during rough weather. He could eat under water, Fleuss says he could stay for a longer period than his ordinary limit of five hours. After his performances under water, Fleuss gave a short, crude popular lecture on his apparatus. He supplies the want of fresh air by taking down with him compressed oxygen to supply the waste in breathing; in other words, he has invented a sort of lungs, which reverse the functions of the natural lungs. This recalls Prof. Tyndall's respirator for firemen, which has proved so valuable in practice, by enabling them to breathe what air is left among smoke and noxious vapors. Fleuss' method is more effectual because he carries his supply of oxygen in a compressed form, and is thus enabled to breathe under conditions in which there is no appreciable quantity of air. He states that he has gone through "fire damp" (carburetted hydrogen), and "choke damp" (carbolic acid), and that he could exist in the charged receiver of a gas factory. In the great helmet and in the hollows of his armor there is room for a certain quantity of air, and this is kept fresh and constantly renewed by a stream of oxygen, the pressure of which he regulates at will. This apparatus is said to be very ingenious, and he will employ it in experiments on the submarine use of the telephone.

The firm that has been awarded the contract to construct the debris dam on the Yuba river advertises for 300 laborers and 150 teams.

Outside of the Comstock.

Among that group of mines classed as "outside"—that is, outside of the Comstock—the Monte Cristo is becoming noteworthy. It is yielding paying ore at the slight depth of 150 ft., and the ore is worked at a water-power mill in Six-Mile canyon. The *Virginia Enterprise* says of this interesting property: We hear but little said about this mine, though ore is being regularly extracted from it in a small way. The lead on which it is situated is one of the strongest and best-defined in the country outside of the Comstock. On the same vein are situated the Occidental, Alabama and St. Johns mines. All these have yielded ore that would pay for milling, and a great deal of money has been taken out of the Occidental. It is undoubtedly a true fissure vein. Evidence of this is seen at the Occidental mine, where the walls have been polished by friction. In one place the west or foot-wall projects to the height of many feet above the main body of the ledge, and is as smoothly polished as though it had been ground down by a lapidary. The scratches seen on

The Coleman Tappet.

One of the most troublesome parts of the stamp battery is the tappet. Its frequent slipping, causing delay and stoppage, is a constant source of annoyance, while the bursting of a tappet by too tight driving of the keys is of common occurrence, and forms an item of expense in the running of a quartz mill. The keys also need repairs and renewal.

The Coleman tappet was designed to overcome the above causes of vexation and expense. In this tappet is applied the principle of the compound wedge: *c c* are the gibs and are wedge-shaped; *b* is a forged steel key, terminating in a thread with a nut, while *a* is an elliptical spring which holds the nut in its place and keeps it from jarring loose. It will be readily observed that the drawing up of *b* forces the gibs, *c c*, to spread apart, and in so doing they are brought into perfect contact, and bug the stem with their entire surface; no heavy hammer is necessary; no driving of keys is called for. A small 12-inch monkey-wrench is sufficient; with this tighten the nut, and the tappet is as solid on the stem as if it were part of it.

The following advantages are claimed for the Coleman tappet: 1. It is stronger than any other tappet, as its strength is not cut away in placing the keys outside the gibs. 2. Having a bearing the full length of the gibs, it is superior to the old style, which bears only at or near the key, both on the stem and back of the tappet. 3. It is less apt to be hurst, for it is tightened with a screw, doing away with the jar and uncertainty of a hammer; at the same time a man is better able to judge of the strain or adjustment.

To the objection which might be raised that "it is impossible to hold the tappet in its place with a nut and screw," the agents answer that the use of the improved key gives sufficient purchase to hold the tappet. To a second objection "that the nut will jar loose," they answer that any nut that is tight enough to vibrate with the stem will be sure to stay in place, as if there was no vibration or jar. The most potent reasoning, however, lies in the fact that the tappet holds and the nut stays in place at the mills in which it is being used. These tappets are on exhibition at the Mechanics' fair. The agents are Adams & Carter, room 7, No. 109 California St.

A MINING TOWN BURNED.—The town of Eureka, one of the most important mining camps in Nevada, was the scene of a very destructive fire on the morning of Tuesday, the 17th inst. It was nearly as extensive as the fire which occurred there about a year ago. The fire broke out in a building south of the Odd Fellows' hall, on Main street, and as the wind was blowing violently, the flames spread rapidly and were soon beyond control. The course of this second conflagration was almost the same as that of last year's. All the principal buildings on Main street were destroyed, while everything to the northward was literally swept off by the flames. The fire also spread to the streets occupied for residence, and so sudden and fierce was the attack, that almost nothing was saved by the residents. It is estimated that one-third of the newest and most valuable part of the town has been reduced to ashes. Among the large establishments burned are the office of the *Daily Leader*, Wan's brewery, the International hotel, the Jackson house, etc. The loss is enormous, and is estimated at \$750,000. As a number of families have been rendered homeless, discomfort and perhaps distress are inevitable.

VALUE OF INDUSTRIAL EXHIBITIONS.—Our Centennial exhibition gave American manufacturers plenty of evidence of the value of such displays in extending the market for their productions. The exhibition at Sydney, New South Wales, has proved similarly useful. The display there of some street motors by the Baldwin Locomotive Works, we are informed by the *Springfield Republican*, brought orders for 27, in addition to those displayed at the exhibition.

SAN FRANCISCO'S WEALTH.—The Auditor of the county has submitted the following compiled statement to the State Board of Equalization as required by the law: Value of real estate in San Francisco, \$122,029,868; value of improvements on real estate, \$42,968,640; value of personal property, exclusive of money, \$68,774,195; amount of money, \$19,747,623. Total value of all property, \$253,520,326. Last year's statement is as follows: Real estate and improvements, \$166,429,845; personal property including \$7,388,635 cash, \$51,027,229. Total \$217,487,074. Excess this year, \$36,033,251.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eps

Something of Bodie District, Mono Co.—No. 1.

The account must be brief—not intended to be exhaustive. The richest and best developed mine lies along an elevated ridge, embracing an area of two miles in length by from two to three furlongs in width, extending from Bodie bluff on the north to Queen Bee hill on the south, the intermediate ground being known as Silver hill. The formation is understood to be a trachytic diorite, better known perhaps as hard-eye or some other species of porphyry.

The discovery of the district dates back many years, but the period has been short since it began to make any very rapid strides.

From statistics gathered at the express office in Bodie, the amount of bullion shipped to date (August 1st) may be set down in round numbers at \$7,000,000—from the Bodie Con. about \$2,000,000, and something upward of \$4,000,000 from

The Standard Con.,

Which ranks first and foremost among the dividend-paying mines of this State. Its claims cover a wide field on Bodie bluff, and immense ore-bodies are still in sight. Its past and present are too well-known to require more than a passing notice. Its almost unparalleled success has given an impulse to mining developments here, the benefits and magnitudes of which are as yet scarcely felt, but will be more fully realized from year to year as company after company steps to this front with its dividends. There are now running not less than seven mills, aggregating 120 stamps—the Bulwer-Standard of 30 stamps being a model of its kind on the coast, averaging from month to month its 120 tons per day.

The total capacity of all the stamps cannot fall short of 400 tons per day, yet failing to meet the requirements, as there is at least one or two mills in process of erection, and from four to five in contemplation. In addition to this a foundry is in operation, with machine shop connected, prepared to do all kinds of casting and machine work for mills or mines, the capola and crane of full capacity of heat for all present demands. This establishment is not only a great convenience, but in some cases almost an absolute necessity to the mining companies, which, it is hoped, they may never fail to appreciate. Beginning at

Queen Bee Hill

On the south, some mines may be described a little in detail somewhat, though not strictly in order of location on the hill—a few prominent ones receiving no mention mainly from lack of opportunity of interviewing superintendents, to whom you are almost solely indebted for any facts (or fictions if any) that may follow.

The Queen Bee mine is situated on this eastern slope of the hill honored with its name, and has a working shaft to the depth of 400 ft. From this station a crosscut has been run to the ledge, on which a drift has been pushed south 260 ft. and another north 550 ft. This vein is represented as large, carrying some good bunches of ore, and as a prospect that will bear following down. For this purpose machinery has been provided capable of reaching a depth of 1,500 ft.

The University,

On the summit, has been prospected to the depth of 328 ft.; five different veins cut, varying from 2 to 22 ft. in width; assays of the ore going from a nominal sum to as high as \$900; quartz from the 22-ft. vein averaging about \$30 per ton, principally gold. The main shaft, which is now being sunk as fast as the nature of the case will admit, is down about 670 ft., the machinery having a capacity equal to the task of lowering to the depth of 1,500. When the 750 level is reached, a drift will be run for the ledges previously cut.

The Maryland Con.,

In the same vicinity, has also some five ledges, rock running by assay from \$30 to \$150 (silver and gold), some very rich ore specimens being shown from both the 300 and 500 levels. Their engine cabling is of Rohling & Son's best steel, guaranteed to sink 1,500 ft., using cars and cages. Developments go steadily forward. Extracting of ore to commence as soon as the mill in contemplation can be erected.

The Boston Con.

Is working a shaft 300 ft. deep. At the 200-ft. station vein formation between walls is 34 ft. in width. A body of ore, full four ft. in width, on the foot wall, has been developed for 275 ft. in length.

A vein of similar character has also been cut on the 300, and drift pushed on the same 109 ft. An air shaft has been lowered 300 ft., which will soon connect with both levels, when hoisting of ore will begin in earnest. Some remarkable assays reported, one rising \$80,000. The estimate of the ore for milling is put at an average of \$40 per ton.

The Noonday and North Noonday, Located on the southern part of Silver hill, which have already shipped in the neighborhood

of \$300,000, have large ore bodies in sight on the 212, 312 and 412 levels, enough to keep their 40 stamps lively for two years to come.

At this 512 level, their deepest workings, the lode is 20 ft. wide (all ore), working from \$40 to \$50 per ton. Some of the ore, if selected, would run up to very high figures. At this station, near the vein, the company has a pair of Niles' engines, 10x12 cylinder, a large 14-inch pump, and a giraffe for the incline now down from 60 to 70 ft.—the whole run by compressed air, which will much facilitate further sinking and the extracting of ore from these lower levels.

The Booker,

Located in the same vicinity, on the western slope of the ridge, from both the 200 and 300-ft. stations, has developed a good strong vein of rather low-grade ore, which it is thought will be eventually worked.

A crosscut is being at present vigorously pushed for the east or principal vein from this 500-ft. station. It is likely to be reached at any day, as it has already advanced nearly 300 ft.

The Red Cloud,

Which is understood to be chiefly under the management of the Noonday company, is one of the most needed and important enterprises of the district.

Taking advantage of the lesson learned by a little Virginia City experience, the shaft was located considerably east of Silver hill, and is now being enlarged to three compartments. It is designed at present principally as a pumping shaft to drain the Noonday and other mines on the ridge, and possibly as a future working shaft when great depth is attained, as the main veins on this part of the belt at least have a decided eastern dip. The machinery, which is sufficiently powerful for all demands for many years, is all on this ground, and is being put in place with all possible dispatch.

The Oro Mine,

On the summit of Silver hill, is opened by a shaft 475 ft. and three crosscuts. On the 230 level a solid body of ore (18 ft. wide) was cut into on the west side, showing a beautiful black, smooth wall, the crosscut afterwards running through vein matter 160 ft. further to the east or hanging wall. The same vein has since been laid bare on the 340 level, from which some 400 tons have been extracted. Some very rich specimens are to be seen at the mine, the ore bearing a very striking resemblance to some of the rich ores of the Comstock. A streak from 8 to 24 inches in width has recently been found running along the middle of the vein, which has given assays as high as \$4,000, average working values being set down at about \$450 per ton, going from 60% to 80% in silver. Fifteen tons were lately shipped to San Francisco to be worked. It is understood that arrangements have been made with the Dunderberg mill, soon to be completed, to crush the rock.

The Champion's

Main shaft is 600 ft. In cross-cutting on the 400 level three ledges have been cut, averaging five ft. in width. A winze has been sunk 160 ft. on No. 3 ledge passing the entire distance through quartz, which has given assays from \$40 to \$200 per ton. On this 550 level two other veins have been cut, the ore represented to assay about \$100. The water is handled by a fine 12-inch double-acting Cornish pump, from the Risdon Iron Works of your city.

The Addenda.

An incline was originally sunk on the vein 475 ft. The character of the quartz seemed to improve all the way down to the lowest level, where a fine large body of good milling ore was laid bare, similar to that found in the Oro.

For convenience of working a new three-compartment shaft was afterwards started 300 ft. east of the incline, and is now down 520 ft. A station was opened at this 500 level and a crosscut made to the ledge. The entire distance from wall to wall measures at this point 40 ft.; width of payors from seven to eight ft. A drift has been run some 60 ft. on the lowest level, the whole distance through fine milling ore, some of it more than ordinarily rich in black sulphurets and ruby silver. It may be looked upon as quite a nice little bonanza. The average of seven assays was \$278, about 40% gold and 60% silver. Another station has been opened on the 400 level to connect with the ore chamber in the old works.

A notice of some of the mines on Bodie bluff will follow next.

A. C. K.

PROPOSED OCEAN TELEPHONE.—A Cincinnati company, says the *Iron Age*, is negotiating with the cable companies for the lease of a line for eight days for the purpose of testing experiments for telephonic communication with Europe. It is believed that the new French line will be secured. The arrangements, it is thought, will be completed in a few days. The process upon which the proposed work is to be done is based upon the Oranibon invention of 1868 and the recent Klemm patents. The tests will be made from New York city. Only the combination of the two systems mentioned will be tested, to the exclusion of the Bell, the Edison or any of the instruments now in active use, as the new company claim that they are actually infringing.

THE production of the South African diamond mines still continues to be enormous, and the statement is made that the quality of the stones, which is frequently marred by a slight tinge of color, is improving.

Hydraulic Pumps on the Comstock.

Good progress is being made at the Chollar-Norcross-Savage shaft in the work preparatory to putting in the new hydraulic pumps. In these pumps a column of water will be made to take the place of a pump-rod. There will be a large iron pipe leading from the surface to the 2400 level to two pumps stationed at that point. At the bottom of this pipe there will naturally be great pressures, but this will be vastly increased by the down stroke of a huge piston working in a cylinder forming the upper part of the pipe or column. It is estimated that the pressure exerted at the pumps on the 2400 level will be about 5,000 lbs. to the square inch. When a stroke of the piston at the surface has forced a portion of the column of water through the pumps and caused it to make a stroke, this water will rise through a return column, ready to be again forced down by the plunger at the surface. Thus this water will move between the top and bottom of this shaft like an endless belt, the same water being used over and over. The water forced up by the pumps will rise to the 1600 level (a distance of 800 ft.) and will there be discharged into the Suto tunnel.

Could the water of the return pipe also be discharged at the Suto tunnel level it would be a great gain, but owing to the great cost of water for this use (it being necessary to buy all used of the Virginia City and Gold Hill Water Company) this cannot be done.

This lift on the return column from the 1600 level to the surface is compensated for, however, by the pressure given by means of the piston forced down upon the descending column of water by a powerful engine. Had they at the shaft a large stream of fire water, the pressure of the descending column would alone furnish sufficient power to drive the pumps, as the water in this return column could then be discharged into the Suto tunnel, 1,600 ft. below the surface.

The new plan does away with the cumbersome and ponderous balance hoists and pump rods and reduces the liability to troublesome delays by breakages, but the pipes used must be of immense strength to stand the great pressures. Experiments are now in progress in San Francisco for the purpose of ascertaining the thickness of iron or steel that will be required at various points in setting up the apparatus.

The two pumps will send up to the Suto tunnel level 1,600 gallons of water per minute. The present pumps raise 1,000 gallons per minute, therefore in all 2,600 gallons will be sent up by all the pumps. Quits a river! At each stroke of the pumps at the 2400 level a certain quantity of water will be discharged into the Suto tunnel—that is, as much water as is forced in at the bottom of this pipe will come out at the top. It is expected to have this new pumping apparatus in operation by the 1st of January next.—*Enterprise*.

An Odd Accident.

A curious accident happened up at the Park the other day, briefly noticed at the time, but which, upon hearing in full the particulars, assumes the characteristics of a phenomenon out of the usual nature of things. It was this accident which occurred to Mr. Dave Clark, well known in this Territory. He had gone into a bath-room, and had disrobed himself preparatory to the business in hand. In one of the pockets of his coat were about 40 dynamite caps, exploded by electricity. From the head of the cap two wires protrude, and the cap having been fitted on the cartridge, the wires are connected with a battery and the charge fired. Occasionally, as is well known, the air becomes heavily charged with electricity, and this result is sometimes disastrous. On this occasion Mr. Clark, after hanging up his coat, shook out of the folds some other garment, and a terrific explosion occurred. The air was heavily charged with the electrical fluid, clouds were overhanging the Park, etc., and it is supposed that the shaking of the garment acted in some manner in increasing the electricity, or putting it into increased activity. At all events the caps exploded, and Mr. Clark, who, very fortunately, was standing with his back towards the coat, was covered with small wounds which the copper pieces inflicted. The coat was torn to shreds, and the boards against which the coat hung were perforated with the pieces of flying metal. When the power of the caps is taken into consideration, the escape of Mr. Clark may be considered very strange, but not more strange than was this cause curious, a sufficient amount of electricity in the air to explode the caps.—*Salt Lake Tribune*.

STEAM ON THE ERIE CANAL.—Since 1872 steam has been gradually working its way on to the Erie canal. After various experiments as to the style of craft and mode of propulsion, a company has at last been organized, in accordance with the laws of New York State, under the name of the Canal and Lake Steamboat Company. The *Commercial Advertiser* says that the company is financially strong, and should the present venture prove as satisfactory as anticipated, funds for placing a numerous fleet of steamers in operation will be forthcoming. The company has already constructed, or has in process of construction, ten first-class, full-sized steamer canal boats. Seven of them will be built at Ithaca and three at Tonawanda. The engine will be of the style known as the compound condenser.

Gravel Mining in Nevada County.

The editor of the *Transcript*, Nevada City, has visited the various mining camps of the county and published accounts of them in his paper, from which we give the following summary of operations in the vicinity of Moore's Flat and Snow Point. Owing to the severity of last winter mining was begun this season later than usual. At and about Moore's Flat the outlook is very promising.

The Illinois claim, owned by Thos. Dowling and situated at the old town, has been an extensively paying property in the past, and is as yet far from being worked out. No work was done there last year, and when it was resumed this spring a landslide occurred, filling up the tunnel and causing a delay for two months. Some 15 men with monitors are now at work washing good gravel, and a clean-up will be made soon.

The Wa Yen Co. employ about 50 Chinamen. At the old town they are working a promising streak with two monitors. East of the old town they are running a hedrock tunnel into what is known as the Bell ground (the Ohio, Paradise, Paradise Lost, etc.), and expect to reach the channel about Christmas. They are putting a Burslugh drill in place to assist them in hastening this conclusion of this undertaking. The Wa Yen Co. is credited with having cleaned-up over \$50,000 last year.

The Boston, at Woolsey's Flat, has been the property of the Eureka Lake Co. for three years past, and is under the superintendence of R. McMurray. About 90 men are employed, and six monitors are in use. The channel here is extensive and rich, and the claim is reputed to be paying large dividends.

The Bluehanks, adjoining the Boston, is owned by four practical miners. It is thought to be one of the best properties of its size on the ridge. As the washing in the Boston claims also removes a large part of the top dirt in the Bluehanks, the latter company are "resting on their oars" for the present. They have done no work there for two years now, but will resume next season.

Blackwell & Wand's recent development at Snow Point continues to hold its own, notwithstanding this prophecy of certain croakers that it would "peter out" before the news of the strike had gone the round of the newspapers. As many men are employed as can be worked to advantage, and the force is being increased as fast as room can be made. Numerous large nuggets are daily found, and the gravel still averages as high as over. I am assured by the leading mining men at Moore's Flat that this importance of the development has not been in any respect exaggerated.

Pendleton & Co., who are running a tunnel from the opposite side of the ridge to tap the same channel, are meeting with indications which lead them to believe they will open on pay dirt within a short time.

There are this summer a large number of prospectors in gravel busy within a short distance of Moore's Flat, and several of them have first-rate outlooks. This whole portion of the ridge indeed is in a fair way to regain its old-time reputation as a prolific gold-field.

NYE COUNTY (NEV.) MINES.—This mines of Nye county are attracting considerable attention at present, says the *Belmont Courier*, especially those of Grantsville. It would pay capital to come this way to seek investment. In Philadelphia district there are mines, as good as any in this county, shut down for want of capital to work them. Jefferson is almost deserted, and yet there are mines there that would well repay a judicious outlay for their proper development. The Belmont mine is being worked steadily and producing a fair quantity of good ore. Spanish Belt district, which lay under a cloud so long, is now making a showing through the Barcelona company's mines that will cause a stir before this time next year. There are also good mines at Downeyville, Ellsworth, Lodi, Ophir Canyon, Jett Canyon and Northumberland that would well repay the investment of capital. The mines of San Antonio were rich on top, and are almost certain to prove productive again when properly opened up. The mines at Morey never looked better, and they are producing sufficient ore of a good grade to keep the mill running to its full capacity. There is a probability of operations being carried on on a more extensive scale in the Tyro Con. mines. Altogether the outlook for Nye is better than it has been for years.

THE DISSOCIATION OF IODINE.—Prof. Victor Mayer reported to the German Chemical Society of Berlin, at its last meeting, that he had succeeded in determining the vapor-density of iodine at a considerably higher temperature than before, and that he had obtained values closely approximating to those required on the assumption that the gas, under the circumstances of the experiment, consisted of monatomic iodine molecules. If possible, he proposes to extend his observations to still higher temperatures, and for this purpose will employ the lately-described oil-furnace of Deville and Troost, which is capable of fusing porcelain.

The number of submarine cables at present in operation is said to be 555, with a cable length of 69,500 nautical miles.

COTTON goods manufactured in South Carolina are now selling in New England.

MECHANICAL PROGRESS.

Welding Iron and Steel.

German engineers are now discussing eagerly a question which has seriously engaged attention in this country, and though nothing conclusive has been reached abroad, it will be profitable to review briefly the conflicting opinions offered, based upon experience and in some cases upon experiments of a specific character. The last German engineer to take up the subject is Herr C. Petersen, of Eschweiler, from whose paper, read before an association of railroad engineers, we glean the following: The welding of iron is dependent upon its property to assume a pasty state within a certain range of temperature, and it may be stated in a general way that the facility with which the welding may be performed is dependent upon the duration of this peculiar condition.

Leaving out of consideration other circumstances affecting welding, it is conceded by the majority of metallurgists, that an increase in the percentage of carbon in the iron impairs the property of welding, and it is generally believed that when 2% is reached it ceases entirely. It might be concluded that therefore it is desirable to keep the carbon within the lowest limits attainable, but there is some diversity of opinion on this point, because a second important condition for good welding comes into play. It is necessary, in order to unite two pieces of iron, to make the surfaces to be welded free from any coating of oxide, a matter which is generally reached by fluxing the oxide by means of sand, borax, etc.; and some hold that a certain percentage of carbon is necessary in order to afford material for the reduction of this oxide.

Welding, among others, maintains that such is not the case, and the silicate of iron contained in wrought iron plays an important role. These theoretical considerations have quite recently become of considerable interest, because they may offer a clue to detecting the reason why the steel produced by the open-hearth and Bessemer processes is generally inferior as regards welding power to wrought iron, an inferiority which stands in the way of the more general adoption of steel in place of wrought iron. The former, it is true, can be welded, but there are many practical difficulties. Certainly steel-headed rails show a case of good welding, and tires, tubes, etc., have been made of Bessemer steel on a large scale, but still steel cannot compare in this respect with wrought iron. It is said that hot working in the Bessemer converter or open-hearth steel furnace favorably affects the welding power, and this is explained by pointing to the fact that hot steel will contain a smaller amount of oxide mechanically mixed than that produced at lower temperatures.

Herr Petersen claims that silicon is injurious, while Herr Kochler, of Bonn, during the discussion following the reading of the paper, held that it was not alone not injurious, but actually favorable for good welding. Herr Helmuth took a different view, and stated that at Bochum, during a series of experiments in an open-hearth furnace, they tried keeping the silicon low, but reached no results, and were similarly unsuccessful by increasing the percentage of phosphorus. They then turned to the Bessemer process and commenced overblowing, which improved the welding, though not in a sufficient degree. By using oxides of iron, however, they obtained much better results, but they did not follow out the matter, because they found that pieces welded together had a yellow red fracture near the weld, and Herr Gresser, of Grafenberg, added that the same tendency to red-shortness was observed by them when making a weldable material in the open-hearth furnace. In using the Terreneire alloy they found that a good product was obtained by adding about four times as much manganese as silicon. It was, however, abandoned on account of its high price.

Herr Petersen concludes by giving some interesting data in regard to the influence of arsenic upon the welding of iron. A lot of inch rod was rejected on account of difficulty in welding, and it was found that the heated rods had a fatty luster, and that two rods laid one upon another slid off as though the surfaces were polished. This took place, although the balls in the puddling furnaces and the piles welded well. The cause of this anomaly was found to be that the injurious effect of the arsenic came out strongly only after the carbon had been considerably reduced. The following analyses are given as representing the composition of the pig used in making these rods, the first being white, the second gray pig:

Sulphur.....	0.774	1.843
Phosphorus.....	trace	trace
Copper.....	0.030	0.580
Arsenic.....	4.250	5.000
Antimony.....	1.145	1.068

—Iron.

LUBRICATORS.—The *Young Scientist* remarks: The efficiency of lathes, scroll saws, sewing machines, and even watches, often depends upon the judgment and care used in selecting a lubricator, and this choice is frequently ill made. Common kerosene oil is too often injudiciously used in place of a thicker or more bland oil, because the heat produced by friction rapidly vaporizes the oil and leaves the journal dry.

Crude petroleum, for the same reason, is only fitted for very slowly revolving journals, such as water-wheels. For very heavy machinery, or for gearing, tallow and black lead, rubbed up together, is the best lubricant, and also the best for wagon and carriage axles during hot weather. For light running machinery sperm oil is the best; good olive oil that has not become rancid and acid, is perhaps the second best, and for winter use lard oil is excellent, but is rather too drying to be a first-class lubricant. Castor oil is better for axles in the winter, and black lead with it is a help at any time.

RUNNING LOCOMOTIVES BY ELECTRICITY.—That locomotives can be run by electricity has certainly been demonstrated, not only by Edison but by others also. But whether the use of electricity in that direction can be made practical and profitable has yet to be shown. Edison's little engine at Menlo Park draws a small car up heavy grades and around sharp curves at a speed quite remarkable; and now this bold inventor is baving an electric engine of 100-horse power built, to run between Rockway and Perth Amboy, a distance of eight miles. The new track, it is said, is to have decidedly sensational features, in order to give the fullest test as to what can be done in this direction. It will have several exceedingly sharp curves, one of which will be 30 ft. radius. It will also have some exceedingly steep grades, one of which will be 880 ft. to the mile, and another of the remarkable grade of 2,600 ft. to the mile. A track rising at an angle of half a mile in a distance of one mile, would certainly constitute a very remarkable railway. The grade of 1,980 ft. to the mile, by which the summit of Mt. Washington, in New Hampshire, is reached, is ascended at a very slow pace, and then only by means of a cogged track. We should rather be excused from the first ride up Mr. Edison's grade of 2,600 ft. in a mile over a smooth track, with only electricity as the motive power.

IMPROVED CHAIN MANUFACTURE.—The American Chain Company of New York are manufacturing chains on a new and patented manner of construction. The patent of the new company consists in putting one-quarter more material in the ends of the links, where the strain and friction occurs, than on the sides, where the strain is not so great. They use the same amount and weight of material in a chain of a given size, but claim that by their process it is increased in strength 50%, and in durability 100%. Public competitive tests have been made to show the comparative strength between chains of ordinary make and those which are made by this company. An ordinary chain five-eighths of an inch in diameter stood a tensile strain of ten tons, while a patent chain of the same size stood a strain of sixteen and one half tons before breaking. An ordinary inch chain broke under a strain of twenty-seven tons, while a patented chain of the same size stood a strain of forty-two tons before breaking. The new chains have been used in the lighthouse service along the Atlantic coast for the past year as an experiment, and, it is stated officially, that after being in use that length of time, they were fit for another year's service, although the ordinary chains which have been used heretofore have been renewed yearly, the constant motion of the buoys to which they were attached having worn a one-inch chain, in some cases, down to a quarter of an inch at the end of the link.

HOW TO WELD A BROKEN SPRING PLATE.—Get the length and then take the part of broken plate which is easiest to handle and upset it suitable for welding. Make a piece of iron five-eighths of an inch wide, quite thin at one edge, leaving the other about three-eighths of an inch thick, something like a razor blade. Take a welding heat on the part that has been upset and weld the iron across, having the thick end on the point of the plate. Scarf it for welding, upset the other part of plate and scarf it so that when welding the piece of iron comes between the two steels. In the first heat—it cannot be done in one—don't strike too hard at first, and thin down any thick edges of the scarfs. Take a second heat and the result will be, in the hands of an average smith, a good sound weld. If the steel is at all fiery do not attempt to weld it. Should there be a hole near the broken place, showing, on being heated, any sign of a flaw, make a new plate. The piece of iron welded between facilitates the welding, and also makes up for the length lost in jumping.—*London Coach-Builders' Journal.*

IRON PAINT.—A German paper mentions that a Herr Chr. Spangenberg has patented in Germany a paint composed of pulverized iron and linseed-oil varnish. It is intended for painting damp walls, kettles, outer walls, or, in short, any place or vessel exposed to the action of the open air and to the weather. Should the article to be painted be exposed to frequent changes of temperature, linseed-oil varnish and amber varnish should both be mixed with the paint intended for the first two coats, without the addition of any artificial drying medium. The first coat should be applied rather thin, the second a little thicker and the last in a rather fluid state. It is not necessary to free iron from rust, grease, etc., by means of acid before applying the paint, as superficial cleaning is sufficient. The paint is equally adapted as weather-proof coating for iron, wood and stone.

SCIENTIFIC PROGRESS.

Is Matter Simply a Mode of Motion?

Science has already relegated to the domain of "motion" all such possibilities of sensation as light, heat, electricity, etc., which were formerly defined as imponderable matter; and now comes Prof. Crooks with his alleged "fourth state of matter," involving conditions which seem to make it quite clear that only gases, but even the most solid bodies with which we are acquainted, such as wood, stone, metals, etc., must also share the same fate, and be considered merely as different modes of motion. The Professor holds that a solid is simply an aggregation of molecules, "separated from each other by a space which is relatively large—possibly enormous—in comparison with the central nuclei we call molecules. These molecules, themselves built up of atoms, are governed by certain forces" the chief of which are attraction and motion. Distant attraction is gravitation, but molecular attraction is cohesion. Both are independent of absolute temperature, but "the mass must be able to bear a reduction of temperature of nearly 300° before the amplitude of the molecular movements would cease." What would result from the arrest of these movements, and the actual contact of these molecules, is beyond our conception. All we know of matter is based wholly upon our experience of molecular movements.

The atomic theory of matter was first announced by Boskovich more than a century ago, and the idea that particles of matter are endowed with both attraction and repulsion, which is involved in that theory, has been held by scientific men in general until quite recently. When atoms "are said to touch each other they are by no means in actual contact, but separated by an insuperable repulsive force." This interval of separation may be the five-thousandth part of an inch, more or less. Within this interval, according to Boskovich, if two atoms are brought a little nearer together they will attract each other; if still nearer, they will repel; "but no force, however great, can bring them into mathematical contact." The fundamental assumption was that matter does not continuously fill space. Faraday held that in regard to atoms and the intervening space, space alone is continuous. He further asked, why assume the existence of matter independent of force, and substituted the term, "center of force" for atom. Thus matter, in the ordinary acceptance of the term, disappeared entirely, to make room for the emanations of force, which fill the universe, and atoms to points of force-convergence.

Of late the hypothesis of molecules and atoms has been greatly developed, and their size and motions mathematically measured. This need not be disputed when instruments have been devised by which one million lines can be drawn in the width of an inch, and each line distinctly seen by a microscope. In Boskovich's theory there was no contact of atoms. By the theories of to-day they are constantly coming into contact and violent collision. What we call a solid is the first state of matter, and its molecules are in a constant state of activity. When the temperature of a solid is raised, these molecular movements increase in rapidity and extent of motion, until the mass becomes liquid. Then we have the second state of matter. A still further increase of temperature converts the liquid into a gaseous form, in which the molecules fly about still more freely, and we have the third state of matter. The gaseous condition is one pre-eminently of molecular disturbance, attended with constant collisions with each other and with the sides of the containing vessels. Now, if a gas is so rarified by an approximate vacuum that the collisions of the molecules in their flight are few as compared with the misses, the molecules will obey their natural laws and move in rectilinear lines, like a flight of cannon balls directed to a distant object. This is called by Prof. Crooks the fourth state of matter. The logical inference from which is that what we call matter, whether solid, liquid or gaseous, is nothing more than the effect which the movement of the mass of the molecules exerts upon our senses, as in heat or light.

If we take up a drop of water, the movements of its molecules convey to our mind the sensation of moisture. If we pick up a coin at ordinary temperature, the different motion of its molecules produces upon us an effect which we term metallic, and so on. If the temperature of the coin is raised, a corresponding effect is produced by the change of molecular movement. The Professor holds that the molecule, itself "intangible, invisible and hard to be conceived, is the only true matter;" that the space covered by the motion of the molecules, which is the mass that we call matter, whether gaseous, fluid or solid, "has no more right to be called matter than the air traversed by a rifle bullet can be called lead." From this point of view then matter is but a mode of motion.—*Californian for September.*

INFINTESIMAL FIBERS.—The microscope shows a variation in the thickness of human hair from the 1-250th to the 1-600th part of an inch; but, notwithstanding such fineness, it is a massive cable in comparison with some other

fibers. Thus the thread of the silkworm is many times finer, being from the 1-1700th to the 1-2000th of an inch. This, however, is nothing to the slenderness of the spider's thread, which has been found in some instances to be no more than 1-30,000th of an inch in diameter. The fibers yielded by the vegetable kingdom are also of astonishing minuteness. Thus every fiber of flax is found to be composed of a bundle of other fibrils which are about 1-2500th of an inch in diameter. Similar fibers obtained from the pineapple plant have been ascertained to be no more than 1-5000th or even 1-7000th of an inch in diameter.

Astronomical Observations at Great Elevations.

The progress of modern optics is now furnishing observers with telescopes of a power which exceeds the capacities of our lower atmospheres for their constant employment. The obstacles to definition due to this atmosphere have grown to be so nearly a barrier to any rapid progress, that attention has lately been given to the conditions of vision which it is very commonly supposed will be found to be best on mountain summits. There is no exact information on this subject, however, and Prof. S. P. Langley was therefore led to make some observations on Mount Etna during a visit there in 1878, the result of which he records in the July number of the *American Journal of Science and Arts*. His object was to gather some sort of quantitative estimate of the degree of transparency and definition, to take the place of vague statement, and to give a kind of standard for comparison with sights in our own territory. The station chosen was "Casa del Bosco," at an elevation of about 4,200 ft. The observations were directed to the sole end of determining the character of vision, as tested at night on stars and nebulae, and by day upon the sun. After a limited number of comparisons, he infers that at this station about nine-tenths of the light of a zenith star reaches us, and that only one-tenth is absorbed by our atmosphere. The gain on Etna over a lower station, as tried by the tests of a double star observer, was more in clearness of the atmosphere than in that freedom from tremor which accompanies good definition. The latter was indeed upon the whole better than below, but not conspicuously so.

Prof. Langley concludes, as the result of his researches, that the balance of advantages for astronomical observations is most likely to be found in a dry atmosphere, and certainly at a great elevation. Such elevations have undoubtedly the advantage of diminishing the atmospheric absorption of the more refrangible rays, an absorption so important that it probably cuts off from us the larger portion of the ultra violet spectrum. The gain for observations of precision will be, though positive, not in itself probably such as to justify the difficulty and expense of such a site; but for the study of the nebulae and stellar photometry, the gain is very essential indeed, while for almost every problem in solar physics it may be said without reserve that, for rapid progress, such observation have now become not merely desirable, but indispensable. The summit of a lofty mountain, however, is not a desirable station. At an altitude of 10,000 or 11,000 ft. the observer may still enjoy all the conditions of health that fit him for labor, but beyond this unfavorable conditions increase very fast.

Quoting from his own experience of a stay of ten days upon Pike's Peak, at an altitude of between 14,000 and 15,000 ft., Prof. Langley says that at this height the attenuated atmosphere makes a long stay impossible for some, while even for the healthiest the conditions of life begin to be such as to render continuous hard work scarcely possible. At the same time the mountain condenses about itself continuous clouds, so that, except during a brief period in the autumn, the opportunities for observation are far rarer than on the plains. A dry climate and a table land, at an elevation of something like 10,000 ft., sheltered on the side of the prevalent winds by a mountain range, which precipitates their moisture in clouds that rarely advance beyond the observer's horizon, appear to be the more promising conditions in our present knowledge. Upon the whole, though the ideal station, where atmospheric tremor does not exist, and the observer pursues his studies in an ever-transparent sky, is not to be found on any part of the earth's surface yet examined, we find, says Prof. Langley, within our own territory, in the dry and elevated table-lands of Colorado or New Mexico, every condition which experience points out as favorable.—*Scientific American.*

ELECTRO-DEPOSITION OF BISMUTH.—A series of experiments on the electro-deposition of bismuth, with various solutions of this metal, has recently been carried out in the laboratory of Mr. D. G. Fitzgerald. Sesquioxide of bismuth, dissolved in a hot solution of the double tartrate of soda and potash—Rochelle salt—was found to give excellent results at a temperature of about 160° F. The anode should be considerably larger than the cathode or article to be plated, and the electro-motive force should be between one and two volts. A perfectly adherent deposit of silvery luster, but of a darker color than silver and not liable to tarnish, may readily be obtained on iron or steel, copper or brass.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

silver, proves to carry a preponderance of gold. The assays thus far heard from run from \$26 to \$36 per ton—80 per cent gold. It is claimed that the ledge is more than 100 ft wide in places, and that it can be distinctly traced several miles. Of course the excitement is great and increasing.

The wonderful richness of the Mount Pleasant has already stimulated quartz mining in that district, and this added will soon make Grizzly flat the liveliest camp in the country.

NOTES.—Bernard Lande has bought the Chaparral mine for \$15,000. This mine lies north of the South Fork of the American, and near Chilo Butte bridge. The developments so far made indicate a fine ledge with every prospect of permanence. It is currently reported that the Prospect Flat mine is returning nearly \$1,000 per day. The Texas Hill tunnel of the E. D. W. & D. G. M. Co. continues to make rapid progress. The same may be said of the Colorado River drift.

ITCU STRIKE.—Placer Herald, Aug. 14: Dr. Stone and others, of Auburn, have been prospecting a gravel lead near Hog diggings, in El Dorado county, and last week they reached the bedrock at a depth of 52 ft. At 9 ft from the surface the gravel showed a fair prospect, which improved as they went down, and at the bottom, on the bedrock, they got as high as \$3 to the pan. They are very much pleased, and have already commenced ditting up for hydraulic.

INYO.

WACO STAR MINE.—Independent, Aug. 7: After a suspension of work for several months on this mine, Mr. Barker has recently resumed operations, and results are certainly good promise of a really valuable mine. Surface stripplings show good ore all along the 30 or 40 ft uncovered, and from a 25-ft tunnel 40 odd tons of ore have been piled on the dump. Numerous assays indicate an average value of not less than \$80 a ton, chiefly gold. The pay streak is over 3 ft wide, in about 10 ft of ledge material.

THE SHIVER.—Messrs. Harris & Rhine this week shipped quite a number of sacks of the mixed copper, silver and gold ore from the Hirsch ledge, for a working test in San Francisco. The Hirsch is an extension of the Brown Monster, and is presumed to be a large and valuable mine.

LASSEN.

DIAMOND MOUNTAIN MINES.—Locate, Aug. 6: George S. Pierce visited his mine, on Diamond mountain, last night, and reports work progressing on it very satisfactorily. Since the 7th ult., he has run a drift along the ledge on the 150 level 50 ft, and struck a spur that prospects ledge. A force of men is now at work on the ledge, before he commences the ledge. Mr. Pierce's claim is in a very favorable location, and its developments are indeed flattering.

NOTES.—Messrs. B. Hamilton & Co. are running a drift from their tunnel in the ledge, which shows a solid vein of quartz about 30 ft wide, and prospects from \$15 to \$25 per ton. Mr. Brannan is also doing work on his claim on the same ledge.

MARIPOSA.

HITE'S COVE NOTES.—Cor. Gazette, Aug. 7: The Hite mine continues to yield up its golden treasures to its despoiling owners. There has been late a marked improvement in the mine at various points, and the continuous piling of the 40 stamps, both day and night, on very fine ore, gives the camp a tone of business. Everybody here seems to be kept occupied, and an idle man is seldom to be seen.

SOUTH HITE MINE.—The owners of this property, after 2 years of hard labor and the expenditure of considerable capital, have at last realized their long-expected success. Their tunnel is now in a distance of 800 ft, and has cut the vein at a depth of 500 ft, which shows great strength, and is 3 ft in width, and of good quality. They have drifted on the ore at this point for about 70 ft, and have just let a contract for a raise to connect the 500 level with the shaft, which has reached a depth of 240 ft, and shows a continuous vein of good ore.

THE HITE MINE.—This mine, which is located east of the South Hite company's mill site, is producing some very rich ore. Their tunnel is being run on the vein, and is now in 60 ft. Mr. Bailley, the owner, has about 30 tons of ore on his dump, which I am told is worth from \$100 to \$500 per ton.

THE HITE MINE.—The San Jacinto mine, which joins the South Hite on the east, is opened by a tunnel 300 ft in length, and shows a splendid vein in the face. The tunnel, which is still further east, and on the Hite vein, is working quite a force of men, with flattering prospects.

NORTH HITE & YOSEMITE CO.—This property adjoins the Hite mine on the north. It is a New York company recently incorporated. The mines are to be opened by a deep tunnel from the main Merced river, under the superintendence of Mr. Monnessey, who informs me that work will begin during September.

MONO.

HOMER DISTRICT.—Index, Aug. 6: Jack Hallahan has returned from Virginia City with a stamp prospecting mine, which he intends to locate in this district. The mine is in Bodie at present, but will probably be out in a few days. Mr. Hallahan is thoroughly familiar with amalgamating processes, and will successfully treat any ore intrusted to him for work.

LITTLE EMMA.—This mine is developing into a wonderful bonanza. The rock is fabulously rich and perfectly free. Thursday afternoon we saw Judge Owens pound 4 odd tons of ore, and the next morning 4 odd tons of ore was the product. Some of the pieces would weigh as much as a dollar.

NOTE.—Considerable gold is being produced by pounding up rock and washing it out in pans. Walking around among the miners' cabins one can hear the occupants pounding away night and day.

LUCKY MORTON.—We learn that Mr. Isaac Stead has been mining and for some time has been employed to develop it. The Lucky Morton is the north extension of the May Lundy, and is a splendid property.

BRYANT MINE.—A mighty nice thing has been struck in this mine. A shaft 20 ft in depth has been sunk on the ledge, which is about 5 ft wide. Two ft of it is solid ore so rich that it is good for sore eyes. The pure stuff can be seen sticking out of every piece of the rock. Quite a lot of ore has been taken out and lies on the dump. The Bryant mine is an extension of the May Lundy and Lake View mines, the latter separating it from the former.

NEVADA.

ECREKA NO. 2.—Transcript, Aug. 8: This mine is located on Little Deer creek, and is owned by John Senner, Sr. The ledge, though not of what is known as high grade ore, yet pays sufficiently well to justify the erection of a 4-stamp mill. A new overshoot wheel has just been built and the water turned on last Thursday. The ledge is worked through a tunnel, is large and easily accessible, and judging from the appearance of the plates below the battery after 24 hours' run, promises to yield better returns than were anticipated.

NOTES.—The gravel claims at Liberty Hill and Lowell Hill are panning out first-rate. It is thought next season that these camps will be as lively as any in the county. Liberty Hill is already showing to look splendidly. The owners are more than satisfied with the claim.

GRASS VALLEY NOTES.—Union, Aug. 11: The Tunnel on the Prescott hill ledge has been driven in a distance of over 1,300 ft. A strong ledge of handsome rock shows in the drift, which mills regularly to a fair profit. At the point the tunnel has now reached there is a perpendicular drift from the surface to the level of the tunnel of about 150 ft. The plan is to carry this tunnel right into the Osborn hill range.

EMPIRE MINE.—The pumps have lowered the water in the Empire mine, on Ophir hill, to the 600 level. Everything about the Empire works in good shape.

PRESCOTT HILL MINE.—There is now being a lot of rock crushed in the Orleans mill from the croppings of this ledge. The mine is big showing to look splendidly. The gold being very plentiful though fine.

GRAVEL ITEMS.—Transcript, Aug. 13: The Morgan gravel mine at Lowell Hill is employing about 25 men. The company expects to increase the force to about 50 in a couple of weeks. The gravel that is being taken out pays from \$2.50 to 4 an ounce to the car load.

GRAVEL MINE.—At this mine on Liberty Hill, they have lately started to gravel. Prospecting is still going on, and

will continue to run on the main tunnel. A short time back 30 car loads were run out, and gave a yield of \$775.

RICH PLACES GROUND.—North San Juan Times, Aug. 14: Mr. Riley, who lives a short distance from Columbia Hill, has with others located some placer ground adjoining the Bruley claim on the west. In running a cut Mr. Riley has given the ground a thorough prospecting, and has several times taken out from 50 cents to 5 bits to the pan. He showed us one piece of gold, slightly intermixed with quartz, which weighed 75 cents. The gold in his claim is of a very coarse texture, and the indications are that their mine will pay richly. We are informed that there is a ripple of excitement in that locality, and every foot of ground up there open to location will soon be taken up.

NEVADA CITY NOTES.—Herald, Aug. 12: Hetherington & Hartung, of Scott's flat, have just finished cleaning up, and the result is an unusual profitable one. The North Bloomfield M. Co. yesterday made a large shipment of bullion. Mining at Quaker Hill is almost at a standstill. Quite a number of men are lying idle.

PLACER.

DARDANIELS.—Auburn Herald, Aug. 14: The strike recently made in this mine turns out, on further inquiry, to be a rich one. It is indicated last week. In the claim near the bedrock the gravel is perfectly heaped with gold, visible to the naked eye. On a pretty thorough prospect it turned out from about 75 cents to \$3 to the pan. This is nearly or quite equal the Breco & Wheeler drift claim, the yield of which night, with property be termed fabulous.

CONRAD.—This mine, on Duncan hill, is being vigorously worked by Mr. Conrad. The sinking of the main shaft, which is now down to a depth of 130 ft, is being pushed ahead as fast as 8-hour shifts can do it, and will be continued until a depth of 200 ft is reached, when a station will be opened and levels run.

A GOOD STRIKE.—We briefly mentioned last week that one E. J. Hunter had made a rich strike in an old tunnel in Duncan hill. Since then we have seen some of the rock taken out by Mr. Hunter, and we found it even richer than had been represented. It is like specimens we have seen from the famous Duncan and Shurtliff lead, in the same hill, heavily charged with free gold, and is beautiful to look upon.

QUARTZ DEVELOPMENTS.—Mr. E. W. Roberts has purchased a portion of the old Banvard ranch, 1 mile from town, on which are several valuable mines, which he proposes to develop. A force of men is now at work on one of the leads. The "Oro Fino" shaft, which is now down 40 ft. The vein is 3 ft wide, and the ore mills from \$10 to \$18 per ton free gold, while the sulphates, of which there is from 2 to 3%, go up into the hundreds.

ROCK CREEK NOTES.—The Auburn and Rock Creek mines owned by Eastern capitalists, are situated about 3 miles from Auburn, on Rock creek, and embrace 3 ledges—the Auburn, the Rock Creek and the Bryce. On the Auburn a shaft is down to a depth of 225 ft, at which point the vein is between 6 and 7 ft wide. On the Rock Creek the main shaft is now about 150 ft deep, from which point a level has been run to the east a distance of 194 ft, and the vein is over 10 ft in width. Preparations are now being made by the company for the immediate erection of a fine 20-stamp mill and new steam hoisting works, to take the place of those now run by water.

TRINITY.—A new quartz development, near Damascus, known as the Poole mine, is reported as turning out well. A new 5-stamp mill has been completed at the Decker mine, in Dutch ravine, and is now making its first crushing. Timber and other material for a new quartz mill to be erected on some recently developed lead south of Auburn, has recently arrived at the depot.

PLUMAS.

GENESSEE MINE.—National: While in Genessee valley recently we examined this property, owned by Dr. Quinn. The mill is a 10-stamp, runs by water and seemed to be in good condition. Only a few men are employed taking out quartz, but the property is said to be paying well for the labor. The veins are small, but rich, and much of the ore is gold-bearing. The property has yielded a large amount of money.

NEW DITCH.—An extensive mining operation is being inaugurated in the extreme southern part of the county, and almost on the line, and said to be backed by Boston capital. A large ditch and flume will carry water from South Feather river, a short distance below Little Grass Valley, to the Mooreville ridge, and the flume will be 4 by 6 ft.

GRANITE BASIN.—Lassen Advertiser, Aug. 6: We learn from Dr. Spaulding, who has just returned from a trip to Granite Basin in Plumas county, that the mines are both placer and quartz. The placer mines were discovered in 1854, when they were very rich, and have been worked continuously ever since. None of the quartz ledges, which are numerous in the district, are being worked at present, although the veins are rich and well defined, and free gold is found in the croppings.

SHASTA.

100 AND FIFTY HILL NOTES.—Cor. Reading Independent, Aug. 12: The Chicago mine, located about 3 miles from the town of Igo, seems to be in a very prosperous condition. They are down 220 ft from the surface, and 110 ft from the tunnel. They are in a state of excellent ore that will run \$100 to the ton in silver. The ore vein varies from 12 to 20 inches in width. The mine has shut down for the present, owing to the fact that there is over 200 tons of ore on the dump, and no room for more. Work on the mill, about a half mile below the mine, is being rapidly prosecuted under the direction of Prof. Aarou. They are also building a furnace, in which the ore will be roasted after being crushed.

CENTRAL MINE.—This mine, a short distance from the Chicago, also contains some fine ore, of the same character as the one in the Chicago. Work is being prosecuted slowly.

CENTENAL.—This mine, located at the head of Eagle creek, has been running 2 months. A tunnel 90 ft has been run into the mountain, and it is expected that the main ledge will be tapped upon going 15 ft further. The croppings of this mine are in some places 12 ft wide, and the ore will assay \$50 to the ton in silver and \$250 in gold.

BULL CHOOT ITEMS.—Knox & Co., of the Central mine, are running a 5-stamp battery, and crushing 24 tons per day. The ore will go about \$30 per ton. The shaft is down about 100 ft, and they are now tunneling from the bottom of the shaft. The ledge is about 5 ft wide, and all pay.

REN BLUFF MINE.—This property has a 5-stamp mill running, crushing about 2 tons per day. They expect to stop crushing soon for want of water. Their shaft from the end of the tunnel is down 40 ft. The ledge is 5 ft wide.

NOTES.—Thompson Bros. are down on their ledge about 40 ft; the ore will run about \$20 to the ton. They have no mill, but hire their crushing done. Grant has struck it rich on the Mammoth, the largest mine in the district. They have just commenced prospecting. Oupit & Maloney have erected a 5-stamp custom mill, which will start up soon.

TRINITY.

WEAVER BASIN.—Journal, Aug. 14: Most of the claims in Weaver basin are nearing the close of the cleaning-up process, and we are pleased to know that, without exception, the mines have turned out well for the season of 1879-80. Although the winter was cold and the spring backward, a more than average year's work was accomplished in most of the claims, and the miners generally express themselves well satisfied with the result.

TAYLOR FLAT.—Cor. Journal, Aug. 10: The Trinity hydraulic gold mine, on the extensive gravel beds, is proving richer and richer as they are opened up, and when fairly under way will astonish the natives. In fact they are already astonished at the little work done to get into the auriferous deposit, and that having been reached, in a month or two they may calculate upon a new revelation. Mr. Walker expects to have 20 or 30 men on the mine, or more if he can use them advantageously.

TUOLUMNE.

TUOJA DISTRICT.—Independent, Aug. 14: Parties from this district report rich developments. Messrs. Jack and Dave Coles, late of Sacramento, have purchased 2 claims of Adam Haag, the Lake and Sonora, located on Silver hill. These claims will be immediately opened and developed. In the Rhinedollar, 11 miles north of the above claim, very rich rock has been found, as also in the Fuller, about the same distance south. At the latter 2 shifts are working day and night. The ore is extremely rich in silver and gold. The ledge is 30 ft wide on top, and at a depth of 5 ft the increase of width gives assurance of at least a 150-ft vein. Silver hill is about 90 miles due east from Sonora.

NOTES.—It is said that Divoll & Co. have again struck it rich in their famous camp. On Thursday night of last week a sack of rich ore was packed from the mine by 2 men, who had to relieve each other in its carriage. This we learn from an eye witness. John Ferguson & Co., adjoining Clark, Divoll & Co.'s Bonanza claim, on Gold hill, took out \$900 in coarse pieces in short time Tuesday evening. How much since we have not been able to learn.

NEVADA.

WASHOE DISTRICT.

UNION CO.—Gold Hill News, Aug. 18: Not much in the way of crosscutting will be done this week. Winze No. 2 from the 2400 level is sinking as usual. Work south from the shaft and north from the Ophir line on the 2500 level is making excellent progress, and in both places some good-looking quartz is encountered.

SISIRA NEVADA.—The raise from the 2300 level, to connect with the old shaft, progresses as usual. Preparations are making for raising in the ore body encountered on this level in order to ascertain its make and value. The north drift, 2400 level is also running north to afford a base for crosscuts, with which to open up the ore vein in that direction.

CALIFORNIA.—The joint Ophir crosscut east on the 2000 level, from which the winze to the 2300 level is to be sunk, is making about 3 ft per day. The joint raise to meet this winze is also progressing well. The drift north on the 2300 level is also averaging 3 ft per day toward the ore vein south from the Ophir line. The slopes of the 1650 level are yielding as usual of fair-grade ore.

YELLOW JACK.—The east drift, 2328 level, has attained a total length of 235 ft, and the face is in hard rock, carrying seams of quartz and considerable exceedingly hot water. The crosscut east, 2700 level, and 130 ft south of the north line, is in 50 ft, and in vein material.

GRAND.—On the 2400 level the joint Mexican east crosscut is making 5 ft per day through good vein material.

CROWN POINT.—The drift east on the 3000 level is in 230 ft, and about up to the point where it is to be turned south to connect with workings north from the Belcher incline.

CON. VIRGINIA.—Work in the joint Best & Belcher winze, in the crosscut east on the 2300 level and the drift south, 2300 level, to connect with the joint Best & Belcher winze, progresses as usual. The slope on the 1750 level continue their yield of from 160 to 150 tons of ore per day which is of the usual grade.

BULLION.—Running the diamond drill from the 2340 station of the Bullion combination shaft. Fine quartz and low-grade ore only encountered so far.

ALPHA.—The north drift, 2310 level, continues to penetrate quartz and porphyry, and the work of low grade.

EXCHANGER.—The diamond drill run on the 2800 level and in a westerly direction, has encountered some good quartz, but of low grade.

BELCHER.—Running north on the 3000 level, to effect the earliest possible connection with Crown Point on that level, in order to secure necessary ventilation for extending workings south on that level. That connection should be made during the coming week.

AURORA DISTRICT.

PROSPERITY.—Esmeralda Herald, Aug. 14: In the Blasdel tunnel, on this mine, Read & Co. have advanced a distance of 190 ft, working being pushed rapidly to tap the ledge. The great feature in this tunnel is the fine blue clay and porphyry, which has now been penetrated a distance of 50 ft, and the vein is contained in a few hundred ft of the ledge. The dump resembles at this time the dumps on the Comstock.

GRAND TRUNK.—Work still continues on the crosscut. The formation at present is more solid, and every indication is good for striking in a short distance a solid ledge. A drift is being run on ledge No. 1, and the course the ledge takes goes to show that it is merely a part of the mother vein and will be cut in a few hundred ft. The ore being taken from the drift is good milling.

REAL DEL MONTE.—Last Monday a blast was set off in the bottom of the shaft, a piece of flying rock or the concussion cracking the rim of the clock-camera, causing it to lose water. This necessarily stopped operations temporarily in the bottom of the shaft. Sinking will be resumed when the clock is fixed. The diamond drill is still operating on the 500 level.

NOTE.—Two more new iron cars and 2,000 ft of track iron arrived for the Blasdel mines Thursday evening. Yesterday more lumber arrived for the boarding-house.

COLUMBUS DISTRICT.

LUCKY HILL.—True Fisser, Aug. 14: The grading for a road is all finished and the approach to the mine is now very accessible. The cutting of the chamber for the hoisting machinery at the mouth of the winze is also completed and everything is in readiness for the reception of the machinery.

MONTICELLO.—Official Letter: North drift, 24 level, has passed through several strata of fine ore, and has not yet reached the hanging wall. North drift, 3d level, is making rapid progress. Have discontinued sinking shaft for the present. Drift from 1st level, to connect with old workings, doing well. Stopes and drifts in ore are looking and producing well.

SARATOGA.—The Hanke incline is down 160 ft and shows good ore in the bottom. Assays from this ore body show \$685 per ton. A drift was started in a crosscut with the perpendicular shaft. The work of sinking the incline will be resumed as soon as connection is made with the shaft.

POROS.—The mill at Belleville has begun crushing. Sixteen tons are being shipped from the mine daily. Ore is still being extracted from the lower level.

VICTOR.—Eighteen men have been put on this week, and the extraction of ore will be pushed as rapidly as possible. The ore will be shipped to New Boston and milled there.

HOLMES.—The crosscut to the west side of the gulch is still being run as fast as possible. The crosscut is following the ledge, the ore of which is low grade.

GENERAL JACKSON.—The crosscut to the south is still progressing, and is now in a distance of 30 ft. The face of the crosscut is all in porphyry.

WINNERS.—The shaft is now down 132 ft. The bottom of the shaft still shows a heavy body of ore.

EUREKA DISTRICT.

REINSON CO.—London Mining Journal, July 24: During the week the refinery produced four bars to the value of \$55,000. The manager writes that operations both in mines and smelting works have been carried on with the usual regularity. The chambers are all looking well and turning out the usual quantity of good ore. The machinery both in mine and smelting works is all in good order.

RUBY DUNDERBERG.—Latest advices state that satisfactory work continues to be done in the Dunderberg mine, and the drift to the great Home Ticket lode is being steadily advanced. This week's returns show an increase of 25 tons raised, and the quality is reported as very good. It is said that work is to be recommenced at the Bullwhacker mine. The prospects at the El Dorado continue encouraging, and rich ore is exposed.

SOUTH RUBY HILL.—Sentinel, Aug. 14: Our reporter passed this section a few days since and noted a number of very promising mines. Among others may be mentioned the Renown, owned by John Morrison; the Grand Delivery, owned by A. P. Hageman; the Continental (patented), owned by Jack Kermee; the Grand Entry, owned by R. P. McDaniel and others; and the Keen &

Kemp, originally owned by the parties whose names it bears. The Kennew and Grand Delivery are located well up on the ridge, while the others flank the eastern slope.

SILVER PEAK.—This mine also is driving to tap the main mineral zone of the district in the neighborhood of this group. With no bad luck, the tunnel will get in inside of 15 months. It is now making good progress. When it shall have reached its destination, it will go far towards demonstrating the value of the properties above mentioned.

PARADISE DISTRICT.

BULLION.—Reporter, Aug. 14: Our reporter visited this mine lately and found it extensively prospected, but very badly gutted out above the 1st level. This level is run from a point 50 ft below the surface in the main shaft, and the ore has been stowed out clear to the surface of the ledge for a distance of about 100 ft. The ore at present in the slope is of an exceedingly rich character, carrying both native and ruby silver in considerable quantities. The mine has never been sufficiently opened below the 1st level to form the least opinion relative to its value below that point.

NOTE.—The returns from the working of 20 tons of 2d-class ore at the Bullion mill netted \$400. The ore was worked by wet process to \$3 of the battery assay, and the result was gratifying to all parties.

MONT. ROCK.—Permanent arrangements have been agreed upon whereby the ore from this mine will be worked at the Bullion mill. Some 300 tons of ore are awaiting shipment, and we are informed there is an unlimited quantity of ore in sight in the mine.

THE GLOVEY.—This promising prospect improves rapidly as depth is attained. The ledge is now 4 ft wide and carries ore exceeding in richness anything yet discovered in the camp.

PHILADELPHIA DISTRICT.

BREAST.—Official Letter, Aug. 4: I have discontinued the drift south under the Cassell steps for the present, as the water makes the air very poor. The air is also poor in the stopes in north end of mine. Am raising winze from 300 level to connect with north stope, which will give good air in stope. Have to raise the winze 35 ft through low-grade ore.

SPANISH BELT DISTRICT.

BARCELONA.—Official Letter, Aug. 4: Since my last report we have advanced 5 ft in north level, which continues to look well, with walls perfect and ledge well defined, and yields a large quantity of fine ore which assays over \$500, with antimonial and native silver, and rich in gold.

WHITE PINE DISTRICT.

EBERHARDT & AURORA TUNNEL.—News, Aug. 12: U. S. Deputy Surveyor Thomas J. Read came over last week from Eureka and took the measurements of the Eberhardt & Aurora tunnel. The total length of the tunnel was found to be 5,688 ft, and the face about 1,600 ft below the surface. They are nearly through the South Aurora ground, having but 14 ft to run when the tunnel started up Saturday.

WARD DISTRICT.

NOTES.—Reflex, Aug. 7: Col. Elliott, of the Black hills, has bought the Monroe & Linton property at Osceola. He has leased the Spencer mill, and will immediately proceed to crush 100 tons of ore—50 tons from 2 different places in the mine—for the purpose of satisfying himself of its value. The owners are working satisfactorily, of which there is no doubt, he will erect a mill of his own in the vicinity of the mine and work it in a systematic manner.

ARIZONA.

OLONE DISTRICT.—Silver Belt, Aug. 7: Work on the Centennial mine, in Ramboz camp, continues to make satisfactory revelations of the value of the property. The face of the tunnel is in nearly 200 ft. The drift east from the main shaft, on the 60 level, is now 90 ft in length, and shows the well-defined pay-streak to have an average width of nearly a foot for the entire distance, while the vein itself will average nearly 4 ft.

WEST BOWDOEN.—This mine has a 6-ft vein between walls, with a foot of ore assaying \$12,000. These figures seem incredible, but in view of the fact that 2 tons of ore worked at the Mexican mill paid for the mine and expenses to date, goes far to prove it.

MACK MORRIS.—This mine is giving good ore at a depth of 160 ft. There are 6 ft of high grade ore in the winze. They are running 2 cross-cuts, one of them at a depth of 200 ft.

ANDY CAMPBELL.—This mine, which is located at Old hill, has been taking out ore of a very high grade. They have a large quantity of ore on the dump, which we are informed will average \$300 per ton.

NOTE.—We have seen ore from the Orion mine which assays in silver from \$20 to \$120 and \$300 gold.

THE BAY HORSE DISTRICT.—Ariz. Miner, Aug. 6: We learn from Samuel Hill, that this new district is at the junction of the Green valley wash with the East Fork of the Verde river, and that it shows remarkable prospects. AMERICAN.—This claim is an immense deposit of gold quartz, fully 50 ft wide anyway, and horn spoon prospects running from \$25 into the thousands can be obtained at any depth within that width. The wash shows from the wash up the hill about 700 ft, then disappears under a capping of sandstone.

IDAHO.

BAY HORSE DISTRICT.—Yankee Fork Herald, Aug. 7: The company erecting the smelter at Bay Horse creek, about 5 miles from Challis, is pushing ahead as rapidly as possible, and expect to have everything in readiness for starting the works inside of a month. A good wagon road has been built from Challis to the smelter, and roads are being made to the different mines in the vicinity. The group of mines in the midst of which the smelter is located, is famous for the high-grade ores contained therein. The last shipments of the smelter, during the same time, have shown a yield of over 3 seasons past, have netted large profits to the owners.

RAMSHORN BRIT.—On the Ramshorn vein, at the base of the hill, is the Post Boy; next the Utah Boy; then the Ramshorn, and beyond this the Skylark—all showing strong, well-defined ledges, containing 1st-class shipping ores. The Ramshorn has a large amount of ore on the dump, and is being worked. A tramway is being constructed from the mine to the foot of the hill. The mine is looking better than it ever did.

BULL OF THE WOODS.—West of the Ramshorn is the Bull of the Woods, with about \$10,000 worth of ore on the dump and much in sight. One portion of the location is leased, and an excellent quality of ore is being raised.

BEARDSLEY.—The celebrated Beardsley mine, 1 mile from the smelter. It has a fine showing of ore, and is furnishing on contract 15 tons per day to the smelting company.

A GROUP OF MINES.—West of the Beardsley is the Hood, with a large amount of ore out. The Log Cabin, lower down the mountain, has considerable ore on the dump. All the ore on the hill is carbonate of lead, carrying some of the best lead in the district. The Hood shows from some of the assays from 100 to 500 ounces silver. Parallel with the Keno is the Ood Enough, with about 10 tons of 1st-class ore on the dump. There are also 2 extensions of the Ood Enough, both well defined and containing a good quality of ore.

COLORADO.

BOULDER COUNTY.—News and Courier, Aug. 6: A mill run from the Poor Man, in Old Cliff district, went \$399.07 for first-class and \$115.14 for second. This, as well as the Grand Central, is owned by J. J. Richards. The mill returns for first-class, first-class \$2,227.40 and second \$631.35. The former is 50 ft deep, the latter 30.

ANALOGUE TRICK.—Cor. Herald, Aug. 6: I saw some of the richest ore at this mine I have ever seen in Boulder county. It was decomposed tellurium and rusty gold. It is just coming in the vein or pay-streak, is 12 inches wide on the foot-wall, and another pay-streak 4 inches wide in the gangue rock. It is very rich, and runs \$500 per ton.

The wonderful richness of the Mount Pleasant has already stimulated quartz mining in that district, and this added will soon make Grizzly flat the liveliest camp in the country.

NOTES.—Bernard Lande has bought the Chaparral mine for \$15,000. This mine lies north of the South Fork of the American, and near Chile Hill bridge. The developments so far made indicate a fine ledge with every prospect of permanence. It is currently reported that the Prospect Flat mine is returning nearly \$1,000 per day. The Texas Hill tunnel of the E. D. W. & D. M. Co. continues to make rapid progress. The same may be said of the Conn Hollow drifts.

NEW BRASS.—*Placer Herald*, Aug. 14: Dr. Stone and others of Auburn, have been prospecting a gravel lead near Hot diggings, in El Dorado county, and last week they reached the bedrock at a depth of 52 ft. At 9 ft from the surface the gravel showed a fair prospect, which improved as they went down, and at the bottom, on the bedrock, they got as high as 23 in the pan. They are very much elated, and have already commenced fitting up for hauling.

INYO.

WACO STAR MINE.—*Independent*, Aug. 7: After a suspension of work for several months on this mine, Mr. Bowman recently resumed operations, and the results so far indicate a fine ledge with every prospect of permanence. Surface stripings show good ore all along the 30 or 40 ft uncovered, and from a 25-ft tunnel 40 odd tons of ore have been piled on the dump. Numerous assays indicate an average value of not less than \$80 a ton, chiefly gold. The pay streak is over 3 ft wide, in about 10 ft of ledge matter.

ONE SHOT.—*Messrs. Harris & Rhine* this week shipped quite a number of sacks of the mixed copper, silver and gold ore from the Hirsch ledge, for a working test in San Francisco. The Hirsch is an extension of the Brown Monster, and is presumed to be a large and valuable mine.

LASSEN.

DIAMOND MOUNTAIN MINES.—*Advocate*, Aug. 6: George S. Pierce visited his mine, on Diamond mountain, last night, and reports work progressing on it very satisfactory. Since the 1st ult., he has run a drift along the ledge on the 150 level 50 ft, and struck a spur that prospects handsomely. He intends continuing the drift 100 ft before he quits the ledge. Mr. Pierce's claim is in a very favorable location, and its developments are indeed tantalizing.

NOTES.—*Messrs. B. Hamilton & Co.* are running a drift from their tunnel in on the ledge, which shows a solid vein of quartz about 30 ft wide, and prospects from \$15 to \$25 per ton. Mr. Brantman is also doing work on his claim on the same ledge.

MARIPOSA.

HIRE'S COVE NOTES.—*Cor. Gazette*, Aug. 7: The Hite mine continues to yield up its golden treasures to its deserving owners. There has been of late a marked improvement in the mine at various points, and the continuing pouring of the 40 stamps, both day and night, on very fine ore, gives the camp a tone of business. Every body here seems to be kept occupied, and an idle man is seldom to be seen.

SOUTH HITE MINE.—The owners of this property, after 2 years of hard labor and the expenditure of considerable capital, have at last realized their long-looked-for expectations. Their tunnel is now in the distance of 800 ft, and the ore is still further east, and of a fine quality. This shows great strength, and is 3 ft in width, and of good quality. They have drifted on the ore at this point for about 70 ft, and have just let a contract for a raise to connect the 500 level with the shaft, which has reached a depth of 240 ft, and shows a continuous vein of good ore.

HOOPER MINE.—This mine, which is located east of the South Hite company's mill site, is producing some very rich ore. Their tunnel is being run on the vein, and is now in 60 ft. Mr. Balloy, the owner, has about 50 tons of ore on his dump, which I am told is worth from \$100 to \$500 per ton.

ITZES.—The San Jacinto mine, which adjoins the South Hite on the east, is opened by a tunnel 300 ft in length, and shows a splendid vein in the face. The Juniaita, which is still further east, and of a fine quality, is working quite a force of men, with flattering prospects.

NORTH HITE & YOKUMITE CO.—This property adjoins the Hite mine on the north. It is a New York company recently incorporated. The mines are to be opened by a deep tunnel from the main Merced river, under the superintendence of Mr. Hennessey, who informs me that work will begin during September.

MONO.

HOMER DISTRICT.—*Index*, Aug. 6: Jack Hallahan has returned from Virginia City with a 1-stamp prospecting mill, which he intends erecting in this district. The mill is in Bodie at present, but will probably be out in a few days. Mr. Hallahan is thoroughly familiar with amalgamating processes, and will successfully treat any ore entrusted to him for working.

LITTLE EXMA.—This mine is developing into a wonderful bonanza. The rock is fabulously rich and perfectly free. Thursday afternoon we saw Judge Owens pound up 4 lbs of it in a hand mortar. An ounce of heavy, coarse gold was the product. Some of the pieces would weigh as much as a dollar.

NOTES.—Considerable gold is being produced by pounding up rock and washing it out in pans. Walking around among the miners' cabins one can hear the occupants pounding away night and day.

LUCKY MORRIS.—We learn that Mr. Isaac Stead has bought this mine, and that a force of men will be employed to develop it. The Lucky Morris is the north extension of the May Lundy, and is a splendid property.

BRAYST MINE.—A mighty nice thing has been struck in this mine. A shaft 20 ft in depth has been sunk on the ledge, which is about 5 ft wide. Two ft of it is solid ore so rich that it is good for sore eyes. The pure stuff can be seen sticking out of every piece of the rock. Quite a lot of the ore has been taken out and lies on the dump. The Bryant mine is an extension of the May Lundy and the View mines, the latter separating it from the former.

NEVADA.

ERENKA NO. 2.—*Transcript*, Aug. 8: This mine is located on Little Deer creek, and is owned by John Senner, Sr. The ledge, though not of what is known as high grade ore, yet pays sufficiently well to justify the erection of a 4-stamp mill. A new overshoot which has just been built and the water turned on last Thursday. The ledge is worked through a tunnel, is large and easily obtained, and judging from the appearance of the plates below the battery after 24 hours' run, promises to yield better returns than were anticipated.

NOTES.—The gravel claims at Liberty Hill and Lowell Hill are panning out first-rate. It is thought next season that these camps will be as lively as any in the county. The Nevada City mine continues to look splendidly. The owners are more than satisfied with the claim.

GRAND LEE MINE.—*Union*, Aug. 13: The Tunnel on the Prescott Hill ledge has been driven in a distance of over 1,300 ft. A strong ledge of handsome rock shows in the drift, which mills regularly to a fair profit. At the point the tunnel has now reached there is a perpendicular depth from the surface to the level of the tunnel of about 250 ft. The plan is to carry this tunnel right into the Osborn mill race.

SEAR MINE. The pumps have lowered the water in the Empire mine, on Ophir hill, to the 600 level. Everything about the Empire works in good shape.

PRESCOTT HILL MINE.—There is now being a lot of rock crushed in the Orleans mill from the croppings of this ledge, that makes a big showing in the blanket washings—the gold being very plentiful though fine.

GRAND LEE MINE.—*Transcript*, Aug. 13: The Morgan gravel mine at Lowell Hill is employing about 25 men. The company expects to increase the force to about 50 in a couple of weeks. The gravel that is being taken out pays from \$2.50 to 3 an ounce to the ore load.

DEWEY MINE.—At this mine on Liberty Hill, they have lately raised to gravel. Prospecting is still going on, and

will continue to run on the main tunnel. A short time back 50 car loads were run out, and gave a yield of \$775.

RICH PLACER GROUNDS.—*North San Juan Times*, Aug. 14: Mr. Riley, who lives a short distance from Columbia Hill, has with others located some placer ground adjoining the Broadwell claim on the west. In running a cut Mr. Riley has given the ground a thorough prospecting, and has several times taken out from 50 cents to 5 bits to the pan. He showed us one piece of gold, slightly intermixed with quartz, which weighed 75 cents. The gold in his claim is of a very coarse texture, and the indications are that their mine will pay richly. We are informed that there is quite a ripple of excitement in that locality, and every foot of ground up there open to location will soon be taken up.

NEVADA CITY NOTES.—*Herald*, Aug. 12: Hetherington & Hartung, of Scott's flat, have just finished cleaning up, and the result is an unusual profitable one. The North Bloomfield M. Co. yesterday made a large shipment of bullion. Mining at Quaker Hill is almost at a standstill. Quite a number of men are lying idle.

PLACER.

DARDANERES.—*Aurifer Herald*, Aug. 14: The strike recently made in this mine turns out, on further inquiry, to be even richer than we indicated last week. In the chamber which had been reached the gravel is perfect, and the gold, visible to the naked eye, is in a pretty thorough prospect it turned out from about 75 cents to \$3 to the pan. This is nearly or quite equal the Breese & Wheeler drift claim, the yield of which might, with propriety be termed fabulous.

CONRAD. This mine, on Duncan hill, is being vigorously worked by the Messrs. Roberts. The sinking of the shaft is down to a depth of 130 ft, and is being pushed ahead as fast as 8-hour shifts can do it, and will be continued until a depth of 200 ft is reached, when a station will be opened and levels run.

A GOOD STRIKE.—We briefly mentioned last week that one F. J. Hunter had made a rich strike in an old tunnel taken out by Mr. Hunter, and we found it even richer than had been represented. It is like specimens we have seen from the famous Duncan and Shurtliff lead. In the same hill, heavily charged with free gold, and is beautiful to look upon.

QUARTZ DEVELOPMENTS.—Mr. E. W. Roberts has purchased a portion of the old Banvard ranch, 1 mile from town, on which are several valuable mines, which he proposes to develop. A force of men is now at work on one of the leads, the "Oro Fino," the shaft of which is now down 40 ft. The vein is 3 ft wide, and the ore mills from \$10 to \$18 per ton free gold, while the sulphurets, of which there is from 2 to 3%, go up into the hundreds.

ROCK CREEK NOTES.—The Auburn and Rock Creek mines owned by Eastern capitalists, are situated about 3 miles from Auburn, on Rock creek, and embrace 3 ledges—the Auburn, the Rock Creek and the Brave. On the Auburn a shaft is down to a depth of 225 ft, at which point the vein is between 6 and 7 ft wide. On the Rock Creek the main shaft is now about 150 ft deep, from which point a level has been run to the east a distance of 194 ft, where the vein is over 10 ft in width. Preparations are now being made by the company for the immediate erection of a fine 20-stamp mill and new steam hoisting works, to take the place of those now run by water.

TRAVIS.—A new quartz development, near Damascus, known as the Poole mine, is reported as turning out well. A new 5-stamp mill has been completed at the Decker mine, in Dutch ravine, and is now making its first crushing. Timber and other material for a new quartz mill to be erected on some recently developed lead south of Auburn, has recently arrived at the depot.

PLUMAS.

GENESSEE MINE.—*National*: While in Genessee valley recently we examined this property, owned by Dr. Quinn. The mill is a 10-stamper, runs by water and seemed to be in good condition. Only a few men are employed taking out quartz, but the property is said to be paying well for the labor. The veins are small, but rich, and much of the slate is gold-bearing. The property has yielded a large amount of money.

NEW DITCH.—An extensive mining operation is being inaugurated in the extreme southern part of the county, and almost on the line, and said to be backed by Boston capital. A large ditch and flume will carry water from South Feather river, a short distance below Little Grass Valley, to the Mooreville ridge, and the flume will be 4 ft by 6 ft. Most of the ditch is in Plumas.

GRANITE BASIN.—*East*, Aug. 6: We learn from Dr. Spaulding, who has just returned from a trip to Granite Basin in Plumas county, that the mines are both placer and quartz. The placer mines were discovered in 1854, when they were very rich, and have been worked continuously ever since. None of the quartz ledges, which are numerous in the district, are being worked at present, although they are large and well defined, and free gold is found in the croppings.

SHASTA.

100 AND PIETY HILL NOTES.—*Cor Reading Independent*, Aug. 12: The Chicago mine, located about 3 miles from the town of Igo, seems to be in a very prosperous condition. They are down 220 ft from the surface, and 110 ft from the tunnel. They are in a shute of excellent ore that will run over \$100 to the ton in silver. The ore vein varies from 12 to 20 inches in width. The mine has shut down for some time, owing to the fact that there is over 200 tons of ore on the dump, and no room for more. Work on the mill, about a half mile below the mine, is being rapidly prosecuted under the direction of Prof. Aaron. They are also building a furnace, in which the ore will be roasted after being crushed.

CRYSTAL MINE.—This mine, a short distance from the Chicago, also contains some fine ore, of the same character as that in the Chicago. Work is being prosecuted slowly.

CENTENAL.—This mine, located at the head of Eagle creek, has been running 2 months. A tunnel 90 ft has been run into the mountain, and it is expected that the main ledge will be tapped upon going 15 ft further. The croppings in this mine are in some places 12 ft wide, and the ore will assay \$50 to the ton in silver and \$2.50 in gold.

BULL CHOP ITEMS.—Knox & Co., of the Central mine, are running a 5-stamp battery, and crushing 25 tons per day. The ore will go about \$30 per ton. The shaft is down about 100 ft, and they are now tunnelling from the bottom of the shaft. The ledge is about 5 ft wide, and all pay rock. They have 8 men employed night and day.

BLUES.—This property has a 5-stamp mill running, crushing about 2 tons per day. They expect to stop crushing soon for want of water. Their shaft from the top of the tunnel is down 40 ft. The ledge is 5 ft wide.

NOTES.—Thompson Bros. are down on their ledge about 40 ft; the ore will run about \$20 to the ton. They have no mill, but hire their crushing done. Grout has struck it, and when fairly under way will astonish the natives. In fact they are already astonished at the little work done to get into the auriferous deposit, and that having been reached, in a month or two you may calculate upon a new revelation. Mr. Walker expects to have 20 or 30 men on the mine, or more if he can use them advantageously.

TOULUMNE.

TOGA DISTRICT.—*Independent*, Aug. 14: Parties from this district report rich developments. Messrs. Jackson and Dave Coles, late of Sacramento, have purchased 2 claims of Adam Haag, the Lake and Sonora, located on Silver hill. These claims will be immediately opened and developed. In the Rhineland, 11 miles north of the above claim, very rich rock has been found, as also in the Fuller, about the same distance south. In the latter, 2 shafts are working day and night. The ore is extremely rich in silver and gold. The ledge is 30 ft wide on top, and at a depth of 5 ft the increase of width gives assurance of at least a 150-ton vein. Silver hill is about 90 miles due east from Sonora.

NOTES.—It is said that Divoll & Co. have again struck it rich in their famous Bonanza claim. On Thursday night of last week a sack of rich ore was packed from the mine by 2 men, who had to relieve each other in its carriage. This we learn from an eye witness. John Ferguson & Co., adjoining Clark, Divoll & Co.'s Bonanza claim, on Old hill, took out 2000 in coarse pieces in short time Tuesday evening. How much since we have not been able to learn.

NEVADA.

WASHOE DISTRICT.

UNION CO.—*Gold Hill News*, Aug. 18: Not much in the way of crosscutting will be done this week. Winze No. 2 from the 240 level is sinking as usual. Work south from the shaft and north from the Ophir line on the 2500 level is making excellent progress, and in both places some good-looking quartz is encountered.

SIEIRA NEVADA.—The mine from the 2300 level, to connect with the old shaft, progresses as usual. Preparations are making for raising in the ore body encountered on this level in order to ascertain its make and value. The north drift, 2400 level, is also running north to afford a base for crosscuts, with which to open up the ore vein in that direction.

CALIFORNIA.—The Joint Ophir crosscut east on the 2000 level, from which the winze to the 2300 level is to be sunk, is making about 3 ft per day. The joint raise to meet this winze is also progressing well. The drift north on the 2300 level is also averaging 3 ft per day toward the one run south from the Ophir line. The slopes of the 1650 level are yielding as usual of fair-grade ore.

YELLOW JACKET.—The east drift, 2325 level, has attained a total length of 235 ft, and the face is in hard rock, carrying seams of quartz and considerable exceedingly hot water. The crosscut east, 2700 level, and 130 ft south of the north line, is in 50 ft, and in vein material.

OMIR.—On the 2500 level the joint Mexican cross cut crosscut is making 5 ft per day through good vein matter.

CROWN POINT.—The drift east on the 3000 level is in 230 ft, and about up to the point where it is to be turned south to connect with workings north from the Belcher incline.

CON. VIRGINIA.—Work in the joint Best & Belcher winze, in the crosscut east on the 2300 level and the drift south, 2300 level, to connect with the joint Best & Belcher winze, progresses as usual. The slopes on the 1750 level continue their yield of from 100 to 150 tons of ore per day which is of the usual grade.

BULLION.—Running the diamond drill from the 2340 station of the Bullion combination shaft. Fine quartz and low-grade ore only encountered so far.

ALPHA.—The north drift, 2810 level, continues to penetrate quartz and porphyry, the former of low grade.

BRONX.—The diamond drill run on the 2500 level and in a westerly direction, has encountered some good quartz, but of low grade.

BEICHER.—Running north on the 3000 level, to effect the earliest possible connection with Crown Point on that level, in order to secure necessary ventilation for extending workings south on that level. That connection should be made during the coming week.

AURORA DISTRICT.

PROSPECTUS.—*Esmeralda Herald*, Aug. 14: In the Bladell tunnel, on this mine, Read & Co. have advanced a distance of 100 ft, work being pushed rapidly to tap the ledge. The great feature in this tunnel is the fine blue clay and porphyry, which has now been penetrated a distance of 80 ft, and will no doubt continue right up to the ceiling of the ledge and dump resembles at this time the dumps on the Comstock.

GRAND TRUNK.—Work still continues on the crosscut. The formation at present is more solid, and every indication is good for striking in a short distance a solid ledge. A drift is being run on ledge No. 1, and the course the ledge takes goes to show that it is merely a part of the mother vein and will connect with it in a few hundred ft. The ore being taken from the drift is good milling.

REAL MOUNT.—Last Monday a blast was set off in the bottom of the shaft, a piece of flying rock or the concussion cracking the rim of the clock-chamber, causing it to lose water. This necessarily stopped operations temporarily in the bottom of the shaft. Sinking will be resumed when the pump is fixed. The diamond drill is still operating on the 500 level.

NOTES.—Two new iron cars and 2,000 ft of track iron arrived for the Bladell mines Thursday evening. Yesterday more lumber arrived for the hoarding-house.

COLUMBUS DISTRICT.

LUCKY HILL.—*True Figure*, Aug. 14: The grading for a road is all finished and the approach to the mine is now very accessible. The cutting of the chamber for the hoisting machinery at the mouth of the winze is also completed and everything is in readiness for the reception of the machinery.

MOUNT DIABLO.—Official Letter: North drift, 2d level, has passed through several stringers of fine ore; have not yet reached the hanging wall. North drift, 2d level, is making rapid progress. Have discontinued sinking shaft for the present. Drift from 1st level, to connect with old workings, doing well. Slopes and drifts in ore are looking and producing well.

SARATOGA.—The Hanke incline is down 100 ft and shows good ore in the bottom. Assays from this ore body show \$55.80 per ton. A drift was started to connect with the perpendicular shaft. The work of sinking the incline will be resumed as soon as connection is made with the shaft.

POTOSI.—The mill at Belleville has begun crushing. Sixteen tons are being shipped from the mine daily. Ore is still being extracted from the lower level.

VICTOR.—Eighteen men have been put on this week, and the extraction of ore will be pushed as rapidly as possible. The ore will be shipped to New Boston and milled there.

HOLMES.—The crosscut to the west side of the gulch is still being run as fast as possible. The crosscut is following the ledge, the ore of which is low grade.

GENERAL JACKSON.—The crosscut to the south is still progressing, and is now in a distance of 30 ft. The face of the crosscut is all in porphyry.

WISDOM.—The shaft is now down 122 ft. The bottom of the shaft still shows a heavy body of ore.

EUREKA DISTRICT.

RICHMOND CO.—*London Mining Journal*, July 24: During the week the relief and ore bars in the value of \$5,000. The manager writes that operations both in mines and smelting works have been carried on with the usual regularity. The chambers are all looking well and turning out the usual quantity of good ore. The machinery both in mine and smelting works is all in good order.

RUBY-DONDERBERG.—Latest advices state that satisfactory work continues to be done in the Dunderberg mine, and the drift to the great Home Ticket lode is being steadily advanced. This week's returns show an increase of 25 tons raised, and the quality is reported as very good. It is said that work is to be recommenced at the Bull-whacker mine. The prospects at the El Dorado continue encouraging, and rich ore is exposed.

SOUTH BAY HILL.—*Sentinel*, Aug. 14: Our reporter passed this section a few days since and noted a number of very promising mines. Among others may be mentioned the Renown, owned by John Morrison; the Grand Delivery, owned by A. P. Hageman; the Continental (patented), owned by Jack Kernean; the Grand Entry, owned by R. P. McDaniel and others; and the Keen &

Keim, originally owned by the parties whose names it bears. The Renown and Grand Delivery are located well up on the ridge, while the others flank the eastern slope.

SILVER PEAK.—This mine also is driving to tap the main mineral zone of the district in the neighborhood of this group. With no bad luck, the tunnel will get in inside of 15 months. It is now making good progress. When it shall have reached its destination, it will go far towards demonstrating the value of the properties above mentioned.

PARADISE DISTRICT.

BULLION.—*Reporter*, Aug. 14: Our reporter visited this mine lately and found it extensively prospected, but very badly gutted out above the 1st level. This level is run from a point 50 ft below the surface in the main shaft, and the ore has been stowed out clear to the surface of the ledge for a distance of about 100 ft. The ore at present in the slope is of an exceedingly rich character, carrying horn, native and ruby silver in considerable quantities. The mine has never been sufficiently opened below the 110 level to form the least opinion relative to its value below that point.

OHIO.—The returns from the working of 20 tons of 2d-class ore at the Bullion mill netted \$400. The ore was worked by wet process to 83% of the battery assay, and the result is very gratifying to all parties.

MEXICO.—Permanent arrangements have been agreed upon whereby the ore from the mine will be worked at the Bullion mill. Some 300 tons of ore are awaiting shipment, and we are informed there is an unlimited quantity of ore in sight in the mine.

THE GLOVE.—This promising prospect improves rapidly as depth is attained. The ledge is now 4 ft wide and carries ore exceeding in richness anything yet discovered in the camp.

PHILADELPHIA DISTRICT.

BELOMT.—Official Letter, Aug. 4: I have discontinued the drift south under the Cassell slope for the present, as the hot weather makes the air very poor. The air is also poor in the slopes in north end of mine. Am raising winze from 300 level to connect with north slopes, which will give good air in slopes. Have to raise the winze 35 ft through low-grade ore.

SPANISH BELT DISTRICT.

BARCELONA.—Official Letter, Aug. 4: Since my last report we have advanced 5 ft in north level, which continues to look well, with walls perfect and ledge well defined, and yields a large quantity of fine ore which assays over \$500, with antimonial and native silver, and rich in gold.

WHITE PINE DISTRICT.

EBERHARDT & AURORA TUNNEL.—*News*, Aug. 12: U. S. Deputy Surveyor Thomas J. Head came over last week from Eureka and took the measurements of the Eberhardt & Aurora tunnel. The total length of the tunnel was found to be 5,683 ft, and the face about 1,600 ft below the surface. They are nearly through the South Aurora ground, having but 14 ft to run when the tunnel started up Saturday.

WARD DISTRICT.

NOTES.—*Reflex*, Aug. 7: Col. Elliott, of the Black hills, has bought the Monroe & Linton property at Osceola. He has leased the Spencer mill, and will immediately proceed to crush 100 tons of ore—50 tons from 2 different places in the mine—for the purpose of satisfying himself of its value. The ore works satisfactorily, of which there is no doubt. He will erect a mill of 100 tons capacity in the vicinity of the mine and work it in a systematic manner.

ARIZONA.

GLOBE DISTRICT.—*Silver Belt*, Aug. 7: Work on the Centennial mine, in Ramboz camp, continues to make satisfactory revelations of the value of the property. The face of the tunnel is in nearly 200 ft. The drift east from the main shaft, on the 00 level, is now 90 ft in length, and shows the well-defined pay-streak to have an average width of nearly a foot for the entire distance, while the vein itself will average nearly 4 ft.

WEST RAMBOZ.—This mine has a 4-ft vein between walls, with a foot of ore assaying \$12,000. These figures seem incredible, but in view of the fact that 2 tons of ore worked at the Mexican mill paid for the mine and expenses to date, goes far to prove it.

MACK MORRIS.—This mine is giving good ore at a depth of 160 ft. There are 6 ft of high grade ore in the winze. They are running 2 cross-cuts, one of them at a depth of 200 ft.

ANDY CAMPBELL.—This mine, which is located at Gold hill, has been taking out ore of a very high grade. They have a large quantity of ore on the dump, which we are informed will average \$300 per ton.

NOTE.—We have seen ore from the Orion mine which assays in silver from \$20 to \$120 and 80% gold.

TOSCA BASIN DISTRICT.—*Arizona Miner*, Aug. 6: We learn from Samuel Hill, that this new district is at the junction of the Green valley with the East Fork of the Verde river, and that it shows remarkable prospects.

AMERICAN.—This claim is an immense deposit of gold quartz, fully 50 ft wide anyway, and horn spout prospects running from \$25 into the thousands can be obtained at any point within that width. It shows from the bed of the wash up the hill about 700 ft, then disappears under a capping of sandstone.

IDAHO.

BAY HORSE DISTRICT.—*Yankee Fork Herald*, Aug. 7: The company erecting the smelter on Bay Horse creek, about 8 miles from Challis, is pushing the work as rapidly as possible and expect to have everything in readiness for starting the works inside of a month. A good wagon road has been built from Challis to the smelter, and roads are being made to the different mines in the vicinity. The group of mines in the midst of which the smelter is located, is famous for the high-grade ores contained therein, the shipments of which, for 3 seasons past, have netted the owners a profit to the owners.

LAMARSHON BELT.—On the Ramshorn vein, at the base of the hill, is the Post Boy; next the Utah Boy; then the Ramshorn, and beyond this the Skylark—all showing strong, well-defined ledges, containing 1st-class shipping ores. The Ramshorn has a large amount of ore on the dump already sacked. A tramway is being constructed from the mine to the foot of the hill. The mine is looking better than it ever did.

BULL OF THE WOODS.—West of the Ramshorn is the Bull of the Woods, with about \$10,000 worth of ore on the dump and much in sight. One portion of the location is leased, and an excellent quality of ore is being raised.

BEARDSLEY.—The celebrated Beardsley mine is 1 mile from the smelter. It has a fine showing of ore, and is furnishing on contract 15 tons per day to the smelting company.

A GROUP OF MINES.—West of the Beardsley is the Hood, with a large amount of ore out. The Log Cabin, lower down the mountain, has considerable ore on the dump. All the ore on the hill is carbonate of lead, carrying some copper. On the summit is the Keno, with over 30 tons of ore out. Assays of the Keno show 500 to 550 ounces silver. Parallel with the Keno is the Good Enough, with about 10 tons of 1st-class ore on the dump. There are also 2 extensions of the Good Enough, both well defined and containing a good quality of ore.

COLORADO.

BOULDER COUNTY.—*News and Courier*, Aug. 6: A mill run from the Poor Man, in Old Cliff district, went \$39.07 for first-class and \$115.14 for second. This, as well as the Grand Central, is owned by J. J. Richio. A mill return from the last went first-class \$2,507.40 and second \$651.39. The former is 50 ft deep, the latter 30.

AMALGAM THER.—*Cor. Herald*, Aug. 6: I saw some of the richest ore at this mine I have ever seen in Boulder county. It was decomposed tellurium and rusty gold. It is just coming in the vein or pay-streak, is 13 inches wide on the foot-wall, and is a very rich, and runs \$500 per ton.

Address of Hon. A. A. Sargent.

The oration by ex-Senator Sargent at the exercises on opening day, is so admirable that we feel we cannot do our young men a better service than to reproduce it in these columns. Senator Sargent—"the trained and skilled mechanic, who rose, step by step, from the printer's case to the Senate of the United States"—is a forcible illustration of the value and dignity of labor. But the example is not necessary; for in these modern times, as the orator well shows, the world's workers occupy the posts of honor. We commend the oration to a careful reading:

Some years ago, while trying certain actions growing out of the breaking of a great reservoir, I was much struck by observing the concurrence of testimony and judgment of scientific men and that of merely practical men upon the nature of forces and their action on bodies—of those whose theories were gained from study and those whose practical experience was the basis of their knowledge. I was led to appreciate that science guides the worker, sometimes unconsciously to himself, and that the theories of philosophers are but the sum of the practical man's experience, or the deductions of genius from his discoveries. Archimedes did not invent the lever. Workmen whose names have not been transmitted used it for ages before he discovered the conditions of its equilibrium and struck out the idea of a center of gravity for all bodies. The invention of machines to move large masses is older than any human record. The architects of the middle ages had practical knowledge of the strength of materials, and had witnessed all variations of falling bodies before Galileo made his experiments on one and discovered the laws relating to the other. A constant succession of illustrious men have prosecuted the study of theoretical mechanics. Their labors have added largely to the world's knowledge of the laws of force, motion, equilibrium, mechanical principles and advantages. But operative mechanics have kept in the advance, and have furnished the necessary problems and illustrations. The natural laws evolved by scientific research have served as guides for experiment and been useful to explain phenomena. If the results have been sometimes merely speculative, sometimes only curious, often abstruse, yet as often they lay the foundation for further achievements in art and mechanics. Such achievements are the product of the workshop, which is the pioneer in the school of progress; for the real advances in mechanics have come from inventors, who have usually been practical and not scientific men. The latter may have observed the processes secured by the former and determined the rules that secured results; but the workmen have invented these processes and given to the world their industrial operation.

Inventors Usually Poor Men.

It is a singular fact that very many of the inventors of the world have been poor men, most of them getting little advantage from education. Thus Arkwright, who invented the cotton-spinning frame, which revolutionized the business of cotton manufacture, and gave great impetus to English prosperity, was born of parents too poor to give him any education. So humble were his fortunes that he earned his living as a barber, shaving in a cellar for a penny until he was 25 years old. He did not acquire even the rudiments of learning until he was 50 years old. Yet he invented a machine that enabled one man to do the work of 130. George Stephenson, the inventor of the high-speed locomotive, was a fireman in various collieries, and could not read until 18 years of age. His son was the constructor of some of the most remarkable engineering structures of modern civilization. The real inventor of the sewing-machine was a farm laborer in early life, and subsequently a cotton-mill operator. The list could be indefinitely extended were it necessary, but is sufficient to illustrate the fact that advancement in mechanic art springs from the workshop as well as from the scientist's study, and may be the product of the humblest worker.

Schools of Object-Teaching.

Hence, grand exhibitions like your's, calling together the inventors and workers of the coast, enabling them to compare their own with others' achievements—to learn by observation what has been attempted and what accomplished, are schools of object-teaching of the most practical character, appealing to sensitive and receptive minds, educated by their own thoughts and experience to appreciate such advantages to their fullest value. The stimulus of such culture upon average minds is marked by the constant improvement in every branch of mechanics, as witnessed by the patents issued by the Government. Any list of patents gives evidence of restless intellectual activity among our mechanics in improvement upon every possible article of use or luxury—from a lead-pencil sharpener to a piano-forte; from a cheese press to a steam fire-engine; from a horse-rake to a quartz crusher. Wherever there is a want, invention struggles to supply it. A thousand busy brains contend with any obstacle until it is surmounted; and it is often the case that simultaneous discovery leaves a doubt as to the originator of a novel invention. Vast grain fields required increased facilities for cultivation, and miracles seemed to be worked by the machine that supplied the want. Demand for rapid communication created the steamer, the railroad, the telephone, the telegraph. War calls for destructive

agencies, which are supplied by repeating arms, by ironclads, by enormous projectiles. Natural laws are infinite, and their application to the uses of life immeasurable. No one can set bounds to that application, for the admitted impossibility of one generation becomes the accomplished fact in another.

Past and Future Development

We pride ourselves upon the advance that we have made over the ways of our fathers. We enumerate with satisfaction the myriad articles of comfort and convenience which we enjoy that they did not have, and display our opulence in the well-filled aisles of our industrial halls, in a collection of articles the names or uses of which would have been utterly strange to them. Some fanciful poet has recalled to earth, hooted upon sight-seeing, and running over with questions, one of the old Puritans who signed the first New England charter on board the *Mayflower*. Under the guidance of a new-made acquaintance, he is given successive views of the telegraph, the railroad train in motion, gas-light, friction matches, and a multitude of other modern inventions, his amazement increasing until he can endure no more, and vanishes with the declaration that the world is turned so upside down no peace is left within it. Yet the progress of the world during the last 260 years has probably not been greater than it will be during the next period of that length. Imagination cannot divine the various forms of machinery and appliances by which man's mastery over earthly things will be extended; and yet experience forbids us to doubt or limit the results. Bulwer, in his "Coming Race," has sought to give some expression to the prophetic instinct that anticipates strange developments in the future from the restless inventive faculty of man. He causes his imagined beings to navigate the air by artificial wings, with scarcely an exertion. They have power of instant and desolating destruction, by means of a lightning-like fluid called *vril*. So potent is it that wars and even discords have ceased; for a child, by its use, could destroy a city or an army, and contest is useless. Nations must repose in each other's good faith, not upon force, where so fatal an instrumentality is within reach of all. But imaginings, even in the mind of a master of fiction, are slow to discover the fields that invention will conquer in the great hereafter.

An Exhibition of 2180.

What a privilege it would be for this audience to attend an exhibition of the San Francisco Mechanics' Institute in 2180. How absorbing our wonder would be as we passed from article to article, of strange names and uses, and missed the objects familiar to our recollection? Inanimate things would seem endowed with intelligence. A weird world would be opened up, astounding the faculties, all unprepared by experience in the progress that had been made to grasp the marvels surrounding them. It would be a fruitless task to endeavor to anticipate that world where all would be so changed and strange. But we may be assured that mankind will have the better for it. Every valuable invention adds to the sum of human happiness and comfort. It gives man stronger grasp on the powers of nature, solves their enigmas, and makes him more at home, and more the master in the world he inhabits. There is no danger of too much refinement or comfort from such sources. Let invention be stimulated to its utmost, its work is repaid in human good; and those instrumentalities which encourage and reward it are worthy of praise and support.

However much a certain class of observers may be led to deprecate the tendency of modern civilization, and forbode its outcome from the occasional agitations that ruffle its surface, it is demonstrable that the comforts once only in reach of the rich are now more generally distributed; that education, once the privilege of the few, is now attainable by the many; that persevering industry is better rewarded, and a certain test of the general welfare—longevity is considerably increased.

The Homes and Modes of Life of the Common People in Olden Times.

The descriptions by old authors of the hovels and modes of life of the commonality in their days cannot now be quoted lest decency be offended. Erasmus described these things with more vigor than delicacy. Holingshead, in producible phrase refers to the rude way of living of his generation. There was scarcely a chimney to the houses, even in considerable towns; the fire was kindled by the well, and the smoke found its way out by the roof, or door, or n-glazed window; the bones were nothing but watling plastered over with clay; the people slept on straw pallets, and had a good round log under the head for a pillow, and almost all furniture and utensils were of wood. I will not describe the rush-covered floors, where dirt was the chief and obtrusive characteristic. In view of such a picture, let him who will declaim against the progress of invention, the arts and refinement. If these are accompanied with some discontent, they certainly remove many of the reasons for it.

Labor-Saving Machinery.

I believe it is not now considered, except by a few among the more ignorant, that labor-saving machinee are injurious to the working classes. It is generally known that such appliances enormously increase employment for the laborer, while enabling him to perform the work of many. Cheapness, caused by facility of production, vastly increases the market for the product, by bringing it within

reach of wider circles of people. Thus human comfort is increased, while the workmen are fully and profitably employed. The construction of the machines also develop new industries. These things are understood by the industrial classes, and few besides demagogues and the densely ignorant dispute them. The world has made a great advance since mobs destroyed Hargreave's spinning jenny, the Jacquard loom and Timoniere's sewing machine. A million persons are now employed in constructing and working machines, and find ample employment in it, where ten thousand persons found such pursuits yielding only a scanty subsistence before invention had added to human wants and resources. It would seem that no one but an enemy of his kind would wish to turn the world back to the rude implements and processes of our ancestors.

Honor to the Inventive Worker.

The tendency of modern civilization is to honor the inventive worker, and to bestow upon him the praise heretofore reserved for the successful warrior. Nations and monarchs have vied with each other in assembling such at their capitals, and in bestowing high award for excellence in mechanic arts. A distinguished English historian complains of this tendency in England, and ascribes to the exhibition given in the summer of 1851 the effect of causing continental nations, and especially Russia, to believe that the ancient spirit of England was failing her, and to presume to cast affront upon her. In the view of this author an extravagant veneration was evoked for mechanical contrivances, and the very words which grateful nations had wrought from out their hearts in praise of tried chiefs and heroes, were plundered, as it were, from the warlike professions, and given to those who, for their own gain, could make the best goods. He complains that it was no longer enough to say that an honest tradesman is a valuable member of society, or that a man who contrives a good machine is ingenious. More was expected of those who had the utterance of public feeling; and it was announced that glory and honor, even true glory and true honor, are due to him who can produce the best articles of trade. For the glory of the mechanic arts, and in token of their conquest over nature, a cathedral of glass was constructed, enclosing them as in a casket, climbing high over stately elms. Kinglake, who so laments, thinks these things indicated to foreigners that England had closed its grand career by a whimsical act of self-adoration, and, therefore, brought on the war of the Crimea, in the anticipation that England, in its excessive devotion to the arts of peace, would not be an obstacle to continental ambition. That her devotion to the arts of peace did not unfit her for war was illustrated in the Crimea, and it was there shown that a people may combine the possession of military strength, and the spirit to use it, with an appreciation of the victories achieved in peace. The Crimea became the scene of one of the most terrible and prolonged conflicts the world has ever seen, and heroic part was borne in it by the nation that but three years before had proclaimed in the "Cathedral of Glass," at Knightsbridge, "Peace on earth, good will to men."

French Exhibitions.

But England has not been the only nation to crown with honor excellence in mechanic arts. In the spring of 1867 France opened its first "exhibition of the productions of agriculture, manufactures and the fine arts." This took place at the very acme of the empire, and was witnessed by distinguished guests from all parts of the earth. A high wave of prosperity swept over France, only broken and thrown back by the corruptions and ambition of the empire, which vainly sought by this exhibition to seat itself more strongly in the hearts of the French people. It is worthy of note that the means devised for this purpose were a tribute to peace and industry—a concession to the grand influence that the industrial classes are gaining among nations. A government more firmly established in the affections of the people would have gained by this grand exposition. As it was, many of the French people saw in it only an effort to show how great and magnificent in peace was the genius of the Napoleonic family. A late exhibition under the Republic was a grand and imposing spectacle, where the self-crowned people gave garlands of honors to those who excelled in industrial arts. It was a tribute of the people to the artisans and artists of the world, and it has not been followed, as in the case of England, by a long and destructive war, nor, as in the case of the empire, by the fall of a dynasty. France was ennobled and invigorated by its tribute to the genius of industry.

America's Tribute to Industry.

I pass by the exhibition at Vienna, in 1879, where a strong, hereditary power followed the heat of the age, that leads to the recognition and reward of eminence in the industrial arts, to refer to our own great Centennial celebration at Philadelphia, where were assembled, in a grand temple erected to industry, not merely our own peerless inventors and workers, but men of all races and climes, each bringing the choicest fabrics known to the artisans of his land, the cunning inventions, rare works of art, characteristic productions, all the material things which are prized for use or beauty. A great republic, existing by the suffrages of busy millions; a nation which had vindicated in its century's history the dignity of labor, and opened,

THE ENGINEER.

Bridge Building in the United States.

[From an address by O. Channuts, Vice-President of the American Society of Civil Engineers.]

While it is true that bridges were built centuries before engineering was recognized as a distinct profession, it is equally true that engineers are admitted to-day the bridge builders of the world. Our predecessors of earlier days worked in wood and stone, and their rules of construction were founded upon the cut-and-try method. We have now added iron and steel as constructive materials, and it becomes a part of our duty to determine, upon scientific principle, the proper distribution of strains, and the due proportioning of materials to resist them, so as to secure the greatest amount of efficiency at the least cost.

As a temporary expedient, wooden bridges were early built in this country, under the familiar names of the Burr truss and the Town lattice, but after the introduction of railroads it became necessary to provide a more efficient system of counter-bracing than could be attained in the earlier forms of trussing. The Howe truss was invented, and was found to be the simplest and best arrangement that could be adopted. This bridge is undoubtedly the best of its kind in the world, and has been of immense service in facilitating the development of our railway system through what may be called its pioneer stage. From data obtained in the railroad reports of the States of Pennsylvania and Ohio, it is estimated that there are now in the United States about 900 miles of bridges upon our railroads, of which, perhaps, one-third are permanent structures of stone and iron, and two-thirds, at least, are temporary structures of wood, which will have to be rebuilt by our engineers.

The demand for more permanent structures has brought about the substitution of iron for wood. As might have been expected, the forms of trussing with which we were most familiar in wood were the first upon which experiments were made in iron. While, however, our English brethren 30 years ago were building plate girders and tubes, our venerable honorary member, Squire Whipple, was studying the subject, and with characteristic modesty laying down the principles of a science of bridge construction, based upon determining the action of the forces, in skeleton structures, by rigid mathematical calculation. His book, printed by his own hand in 1847, contains nearly all that is vitally important connected with the theory of fixed spans, and his bridges stand today as monuments to his skill and reminders to us of the debt we owe to that distinguished engineer.

The concentration of the material into a few parts resulted in the use of the pin connection at the joints, in contradistinction to the rivet, as used in other countries. For compression members, cast iron very readily adapted itself to top chords and posts, and, until late years, was considered satisfactory.

To resist tension it became necessary to forge bars with enlarged heads, now known as eye-bars, and to determine the proper proportion of pin and eye to the section of the bar, so as to develop its full strength. In this we have been reasonably successful, and, with the introduction of improved machinery, we have been enabled to make and secure uniformly reliable bars at a very low cost. To this fact, perhaps, more than to any other, may be attributed the success which has attended the labors of American bridge builders.

The eye-bar is the distinctive feature of the pin-connected bridge, and upon it depends, in a large measure, its economy.

A bridge which can be taken upon the staging in pieces and made self-sustaining between daylight and dark, would seem to need little more to be said in its favor, as compared with the tedious and expensive methods rendered necessary in the erection of riveted structures.

It must not be assumed, however, that American bridges are all pin connected. Many of the best railroads in the country prefer riveted bridges on account of their superior rigidity, particularly in short spans, and from the fact that they are not easily knocked down by derailed cars, a point which has not received the attention which it deserves. Our shop practice in riveted work is generally good, and we have effected some improvements on the European methods in general design; but we are yet deficient in experimental knowledge as to the value of the rivet connections, particularly when applied on one side of an angle bar, and we have not yet been able to avoid cross straining upon the chord at the intersection of the diagonals.

The English practice of drilling all holes on the ground where splices occur has not been found necessary here when a proper system of automatic spacing is employed.

The chief defects in our bridges have arisen from the weakness of the floor, and when it is remembered that locomotives have increased in weight within the past few years about 40%, and that the floor is subjected to its maximum strain every time that a locomotive passes over the bridge, it will be apparent that a decided increase in strength must be given to this portion of the structure, and in all probability it will be necessary to renew many of our earlier bridges in this particular.

Again, there should be more efficient provis-

[CONTINUED ON PAGE 124.]

ion against disaster from the derailment of cars. The less wood we have on iron bridges the better; ties are, of course, a necessity, but they should be supported on at least four iron stringers, and be spaced 8 to 10 inches apart and secured against spreading. Joint boxes should be avoided. End posts should be continuous to the masonry supports and secured to the top chord and to each other by efficient portals. Horizontal bracing, to resist vibrations and wind pressure, should be made more effective than they are, particularly at the chord connections. There are many other minor details, it is safe to assume, which will be presented in due time, but upon the broad question of experimental information we must look for aid to every member of the profession.

A testing machine of the very best description, belonging to the United States government, is now in working order, at the service of all such as may desire to avail themselves of it. I believe the time has arrived when a committee of this society should be appointed for the purpose of inviting the co-operation of manufacturers in the effort to obtain more accurate knowledge of the metals and manufactured shapes which enter into our important structures.

Particularly is this the case in regard to the material we call steel. Of late, the manufacture of steel by the pneumatic and open-hearth processes has been undergoing a prodigious development, and we may now assume that a metal can be obtained by either of these methods more uniform in its character than the best iron yet offered in merchantable quantities, possessing an elastic limit of 40,000 lbs. per square inch, and an ultimate strength of 65,000 to 70,000 lbs. per square inch, and capable of being manufactured into any of the required shapes for structural purposes, at a cost which, taken in connection with the saving involved in dead weight, must insure its substitution for iron in the larger spans at least; and it is confidently asserted by those whose experience entitles them to speak with authority, that the day is not far distant when steel will be produced at a less cost than iron is at present by the hand-puddling process.

All the more important, therefore, is it that we should inform ourselves by the most thorough tests of the characteristics of steel, if we would maintain the high standard of American bridge construction. We have thus far applied this metal to but few structures. It has been used in the bridge at St. Louis, in the bridge at Glasgow and is now being used in the East river bridge, designed by Mr. Roebling, of 1,600 ft. span, and in parts of the Plattsburgh bridge, which you are invited to visit. It is hoped that the engineers of these pioneer structures will communicate to the society the information which their experiments have elicited concerning this material of the future.

The day cannot now be far distant when the merits and economy of the American type of bridges will be recognized by other nations. Already, notwithstanding the fact that labor and materials are cheaper in other countries than in this, we are able to compete successfully in Canada and South America. I believe that a well-directed effort to make known abroad what we have accomplished in this branch of engineering during the last 15 years would open a market for our bridges and bridge designs in Europe and in Asia.

Water Jet Dredging.

Among the numerous obstructions in New York harbor is, or rather was, Diamond Reef, since a considerable part of the rock has been blasted out. Enormous quantities of debris as well as a bed of hard pan consisting of boulders, gravel and sand remain to be removed. According to *Scribner's Magazine* this work is being very successfully done by means of water jets, in the same way as the gravel rocks are broken down in hydraulic mining. By means of a powerful pump on one of the dredging barges a large jet of water is forced through a hose and nozzle, which are secured in the desired position above the surface of the material to be removed. By means of this sub-aqueous jet the reef was rapidly broken down, and while some of the debris was carried out into deep water, an accumulation of sand, gravel and boulders, etc., soon blocked up the jet and stopped the work. A hydraulic ejector was then contrived consisting of a tube of large diameter, suspended horizontally some distance above the bottom, with one end pointing to the deep water beyond the edge of the reef. The other end of the tube was furnished with a nozzle placed inside it and connected by hose to the steam pump on the barge; the annular space between the nozzle and the tube was filled with a coarse grating to keep back the larger stones. While the first mentioned arrangement was kept in action stirring up the loosened material of the reef, the induced current created by the second jet was sufficiently powerful to sweep all the loosened sand and gravel through the large pipe, and discharge it into deep water. It was also found that if the outer end of the pipe was pointed upwards, and the stream of gravel and water was thrown clear of the surface and could be received in bopper barges, or disposed of in some other way. This idea of hydraulic dredging is not entirely new, but we are not aware of its having been employed before so successfully, or worked out in so practical a manner.—*Engineering.*

USEFUL INFORMATION.

The New German Preserving Fluid.

A new fluid, to be used for preserving dead bodies, has recently been devised, the patent for which the German Government has purchased and given to its people for their free benefit. Several criticisms upon the formula for its manufacture have appeared in foreign journals. Mr. Martenson, of St. Petersburg, says: Alum forms one of the constituents of the liquid; probably potassic alum is meant, and in place of potassa probably the carbonate. But under the circumstances, all the alumina of the alum is precipitated, so that the liquid does not retain any in solution. On preparing large quantities of the solution, the labor of straining or filtering from the deposited alumina is very onerous. It is much better to omit the alum, and to substitute at once that substance which was produced by it in the original liquid, namely, potassium sulphate. A portion of the alum may be replaced by borax, so that the constituents will be the following:

	Parts.
Water.....	620
Potassa.....	10
Sulphate of potassa.....	4
Salt.....	5
Nitrate of soda.....	3
Carbonate of potassa.....	9
Arsenious acid.....	2
Glycerine.....	300
Alcohol.....	50

The arsenious acid and carbonate of potassium are dissolved together by the aid of heat, and added to the solution of the other ingredients.

CLOTH FROM THE DOWN OF BIRDS.—An ingenious Frenchman, M. Thierry Girees, has devised a method, and invented machinery, for the manufacture of cloth from the down of birds. The down may be worked either by itself or in mixture with wool, silk or cotton. The goods produced, whether exclusively of down, or mixed with fibrous material, present entirely novel features and characteristics. It is found that the down, whether of the swan or any other bird, will take any shade of dye, from the most delicate to the deepest color. The cloth is very warm, more so than woolen, and may readily be made impervious to moisture. It has been found best, as a general thing, to mix the down with some fibrous material, and for most uses wool is preferable. Its preparation with wool, in order to make an intimate mixture, oleic acid is used, in certain fixed proportions, during the first stages of the manufacture—in sorting and carding. It is carded, spun, woven, filled and tacked down by special machinery, invented for the purpose by M. Girees. The cloth is much like velvet; the "nap" of the mixed material, after it is finished, consists mostly of down. Shearing and dyeing is effected in the usual way, and, as already stated, this "down" cloth takes any shade of color. *L'Ingenieur Universel*, of July 2d, gives an illustrated description of most of the machinery employed in this new article of manufacture.—*Californian for September.*

HINTS FOR PRESERVING FRUITS.—A useful hint to cooks was given at a recent sanitary convention in Grand Rapids, Michigan. It was pointed out that by adding sugar to sour fruits, during the cooking process, the greater part of the cane sugar was converted by the aid of the acid into grape sugar, which does not possess half the sweetening power. By cooking the fruit first, and then adding the sugar to an agreeable sweetness, a very great deal of sugar might be saved. Raspberry, strawberry, and cherry syrups of the German Pharmacopoeia have to be made by bruising the fruit and letting the juice be strained off and filtered. A better and safer way is to add at once to the freshly bruised fruits five to six per cent. of alcohol, to let the whole stand for some days, decant and filter. Lastly, boil up once to remove the greater part of the alcohol. Syrups made with juice prepared as above retain in a remarkable degree the odor and taste of the fresh fruits.

THE PHILOSOPHY OF DYEING.—A French expert has recently been making some very interesting experiments upon animal and vegetable substances, with the view of ascertaining how coloring matter is taken up by the substances which are being subjected to the dyeing process. It was found that the action depended largely upon the capillarity of the fiber or other substance treated. Microscopical examination of infusorial earth showed that the coloring matter entered the capillary tubes of the infusoria, and attached itself to the inner surface of the walls. So with fibrous material. The more fully the capillary construction was developed, the more perfect is the capacity of the substance to receive colors. This fact will be found of special importance in the art of dyeing, and affords an explanation of the reason why some substances receive dyes more readily than others.—*Californian for September.*

TO RESTORE RANCID OILS.—Fixed oils may be deprived of rancidity by adding a small quantity of sweet spirit of niter and shaking well, and afterward heating slightly till the odor of the spirit has disappeared.

TO CHANGE THE COLOR OF FLOWERS.—The natural colors of flowers may be changed by exposing them to the diluted fumes of ammonia. Most of the blue, violet and light crimson flowers turn to a splendid bright green. Dark crimson clove pinks turn black, other dark red flowers turn dark violet, all white flowers turn sulphur yellow. This change of color is especially beautiful when they are variegated or the single petals possess a different color. As soon as the new color is fully developed, the flowers must be dipped at once in cold water, when they will keep their new shade for two or six hours; by degrees then their natural color returns. If flowers be exposed to the vapors of ammonia for one or two hours they turn a dirty chamois, which is permanent. Blue, violet and red asters are dyed or turned intense red when they are exposed to the fumes of muriatic acid gas; it takes from two to four hours or more before the shade is fully developed. The flowers are then removed to dark, cool rooms to dry.

UTILIZATION OF WOOD SHAVINGS.—From wood shavings and paper Herr Heilmann makes plates, dishes, etc., as follows: Selected plane shavings are bound into bundles, and steeped in a bath of weak gelatine solution about 24 hours, then dried and cut into suitable lengths. Plates are cut of strong paper or thin pasteboard, of the size of the objects to be produced. These are moistened with a liquid consisting of weak gelatine solution with soda water glass and pressed in heated metallic molds. After drying, the pressed paper objects are coated on both sides with an adhesive material made of five parts Russian gelatine and one part thick turpentine; the shavings are applied to them and the whole is subjected to pressure. Wood shavings alone would, because of their unequal thickness, present uneven surfaces. The objects are now cut, if necessary, dried and varnished.

TO PRESERVE AND RENOVATE RUBBER INSTRUMENTS.—It is well known that many articles and instruments made of rubber are apt to become dry with time, and to crack, grow brittle, and lose all elasticity. According to a Russian journal, this may be prevented by the use of a simple mixture of one part aqua ammonia with two parts of water; in which the articles should be immersed for a length of time varying from a few minutes to one half or one hour, until they resume their former elasticity, smoothness and softness.

CABBAGE TEST-PAPER.—A useful test-paper may be made by boiling a pound of the leaves of red cabbage in one pint of water for some time, and then straining the blue liquor through muslin. Evaporate to about half its bulk; place layers of white blotting-paper in the liquid, and then hang them up to dry. Acids change the blue color of the paper to red, and alkalis turn it green. This is a very good substitute for litmus paper.

GOOD HEALTH.

Hints on Sea-Bathing.

August is the month for sea-bathing, which, if properly managed, is one of the most healthful and invigorating of exercises, though its good effects are often neutralized through ignorance or carelessness. The following extracts from Dr. J. H. Packard's *Sea-Air and Sea-Bathing* (one of the "American Health Primers") furnish a very good summary of rules for the guidance of the unprofessional reader in this matter:

How Long to Bathe.—It is quite absurd to lay down positive rules as to the time people should remain in the water, since they do not carry watches in with them. And any day's experience on the beach in the season will show a great many bathers sporting in the water for half an hour or an hour, and even longer, without any perceptible ill effect. It is quite a common practice among the young folks to go in, take a bath, come out and lie on the sand, and go in again, perhaps a number of times. The powers of endurance vary greatly, and it is well known that swimmers have sometimes remained in the water for many consecutive hours without harm.

There can, however, be no question that for sanitary purposes, and as a matter of prudence, it is better to take the bath, and then to leave the water for the day.

What is wanted in ordinary sea-bathing is to carry the chilling of the body only so far as to promote the subsequent reaction. The first sense of cold on entering the water is soon followed by the feeling of returning warmth; and this continues for some little time, to be again succeeded by a sense of chilliness. This second cooling is accompanied by diminution in the activity of the circulation, shown especially by blueness of the lips or fingernails; and this should invariably be regarded as a signal for leaving the water at once. To wait until the teeth chatter, and the skin of the fingers becomes shriveled like those of a washerwoman, is in a high degree imprudent.

For those who have young children or invalids under their charge, and who are able to observe and regulate the exact time of their stay in the bath, it may be said that this may be according to the condition of the skin, somewhere between 2 and 15 minutes. It is always safe to err on the side of prudence, and to cut

the bath needlessly short rather to prolong it at any risk.

Perhaps it need hardly be said that the colder the water is, the less time should be spent in it. When the air and the water are both cold, the duration of the bath should be correspondingly diminished. This condition of things increases the danger of shock and of insufficient reaction.

One should enter a sea bath comfortably warm and exercise actively during the stay in the water. The temporary chilling of the surface will then give place quickly to a glow, which may be kept up or even increased by thorough rubbing.

How to Bathe.—There is very seldom opportunity for diving into the sea, and only a very small number of bathers are expert enough to do it. The best plan is to walk or run rapidly into the water, wading out at once far enough either to dip the whole person, head and all, or to allow a wave to break over the bather. Some like to have a bucket of sea water dashed over them before going in. Once in the water, and thoroughly wet, one need only keep moving, occasionally going under a wave, as long as the water is agreeable, and there is no sense of chilliness.

Swimming.—It is not safe to swim in the sea when the tide is running out, as then it is difficult to make headway towards the shore. It is not safe to swim when there is a heavy surf, as even a good swimmer may be so confused and baffled by waves breaking over him as to lose his presence of mind, and perhaps swim seawards instead of to the shore; or he may be so exhausted by the force of the water as to sink.

It is not safe to swim when there are strong currents running in the general line of the shore, as these sometimes set outward enough to keep the bather in deep water longer than his powers can hold out. Should he find himself in such a current, he should never try to make head directly against it, but should swim diagonally towards the shore, and, above all, should try to keep his presence of mind and save his strength.

On leaving the surf bath it is always best for the bather to wash his head with fresh water, so as to free the hair from salt, which would otherwise make it very stiff and harsh. At many places there are connected with the bathing houses hydrants at a suitable height, by means of which this may be very conveniently done.

Sleeping Position.

The food passes from the stomach at the right side, hence its passage is facilitated by going to sleep on the right side. Water and other fluids flow equally on a level, and it requires less power to propel them on a level, than upwards. The heart propels the blood to every part of the body at each successive beat, and it is easy to see that if the body is in a horizontal position the blood will be sent to various parts of the system with greater ease, with less expenditure of power, and more perfectly than could possibly be done if one portion of the body were elevated above a horizontal line. On the other hand, if one portion of the body is too low, the blood does not return as readily as it is carried thither; hence, there is an accumulation and distention, and pain soon follows. If a person goes to sleep with the head but a very little lower than the body, he will either soon waken up, or will die with apoplexy before morning, simply because the blood could not get back from the brain as fast as it was carried to it. If a person lays himself down on a level floor for sleep, a portion of the head, at least, is lower than the heart, and discomfort is soon induced; hence, very properly, the world over, the head is elevated during sleep. The savage uses a log of wood or hunch of leaves; the civilized, a pillow; and if this pillow is too thick, raising the head too high, there is not blood enough carried to the brain, and as the brain is nourished, renewed and invigorated by the nutriment it receives from the blood during sleep, it is not fed sufficiently, and the result is unequipped sleep during the night, and a waking up in weariness, without refreshment, to be followed by a day of drowsiness, discomfort and general inactivity of both mind and body. The healthful mean is a pillow, which by the pressure of the head keeps it about four inches above the level of the bed or mattress; nor should the pillow be so soft as to allow the head to be buried in it, and excite perspiration, endangering ear-ache or cold in the head, on turning over. The pillow should be hard enough to prevent the head sinking more than about three inches.—*Hall's Journal of Health.*

INSANITY A BOON.—A German physician considers insanity in the light of a boon. This is certainly a novel view. He holds that the loss of reason lands the sufferer from a sea of trouble into one of comparative calm—often into one of decided happiness; and attempts to restore such a person to sanity would be cruel rather than kind. Moreover, he insists that without a certain amount of insanity success in life, in the ordinary acceptance of the term, is quite impossible. All eminent men, he contends, are decidedly more or less mad. Many of them are dangerous monomaniacs whom it would be decided on public grounds to shut up, but who nevertheless achieve grand careers, and are credited with doing a vast amount of good. The false notion he attributes to the fact that the greater mass of mankind are also insane, and quite unable to distinguish between good and evil.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Mears Chlorination Process; Remarkable Performance Under Water Outside of the Comstock; The Coleman Tappet, 118; The Week; The Plague of Experts; Pacific Coast Fish; The Ontario Silver Mine, 120. Leaf Variation in Acacia Trees, 121.
ILLUSTRATIONS.—The Coleman Tappet for Quartz Mills, 118. Leaves and Flowers of the Acacia Melanoxylon, 121.
CORRESPONDENCE.—Something of Bodis District, Mono Co., No. 1, 114.
MISCELLANEOUS.—Hydraulic Pumps on the Comstock; An Odd Accident; Gravel Mines in Nevada County, 115. Address of Hon. A. A. Sargent, 118.
MECHANICAL PROGRESS.—Welding Iron and Steel; Running Locomotives by Electricity; Improved Chain Manufacture; How to Weld a Broken Spring Plate; Iron Pumps, 115.
SCIENTIFIC PROGRESS.—Is Matter Simply a Mode of Motion? Astronomical Observations at Great Elevations, 115.
MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 116.
MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado and Idaho, 116-117.
USEFUL INFORMATION.—The New German Preserving Fluid; Cloth from the Down of Birds; Hints for Preserving Fruits; The Philosophy of Dyeing; To Change the Color of Flowers; Utilization of Wood Shavings, 119.
GOOD HEALTH.—Hints on Sea-Bathing; Sleeping Position; Insanity a Boon, 119.
INDUSTRIAL WORLD.—Enormous Grain Elevators; The Pullman Palace Car Co.; American Watches; Statistics of the Iron and Steel Industry, 122.
NEWS IN BRIEF on page 125 and other pages.

Business Announcements.

Dividend Notice—Eureka Con. M. Co.
Iron Pits Wanted—H. C. Perkins, French Corral, Cal.

The Week.

The Industrial Exhibition at the spacious pavilion of the Mechanics' Institute is now fairly under way, and is attracting daily and nightly a large body of visitors. Apart from the interest which the ordinary visitor feels in the display of the varied products of our industrial establishments, a promenade around the illuminated hall, during which the curious eye is attracted at almost every step, is a source of agreeable surprise, pleasure and instruction. As a place of rest or amusement for the tired man or woman, there is at present nothing in the city half so inviting and refreshing. Then it is such a pure delight to the little folks that, if we could have our way, the fair should be open for ever.

On Tuesday, the 17th inst., a very destructive fire occurred at Eureka, Nev., and burned over an area almost identical with that destroyed by the fire which took place there a little over a year ago. The latest accounts represent that about 300 houses, many of them business establishments, were destroyed. An area equal to 50 acres, situated in the very core of the town, was literally swept by the flames. The loss is estimated at \$750,000, which is covered by an insurance of \$150,000. Eureka is among the most productive mining camps of Nevada, and its business is intimately connected with this city; and that consideration will help to excite the sympathies of our citizens in behalf of the sorely stricken town.

In recording the salient incidents in our industrial progress, it is pleasant to note the enterprise of an incorporation at Oakland, the object of which is to manufacture woolen goods—an industry which is peculiarly adapted to California. The company will begin operations about the 1st of November, and will, at such time as its works shall be completed, give employment to 600 or 800 men and women and boys and girls.

EXTRAORDINARY MILEAGE.—Mr. Watkey, master of machinery of the New York Central and Hudson River railroad, reports that locomotive No. 569, running between Syracuse and Buffalo, with two crews of men, made in 10½ successive months the extraordinary amount of 95,052 miles.

The Plague of Experts.

For many years the mining experts of the Pacific coast have been a distinct and curious class. The larger part delight in the title of "professor." This class embraces every nationality, and almost every trade and calling. As the mining region expanded under new discoveries, fresh experts appeared and swelled ranks that were already crowded to plethora. The supply more than kept pace with the demand. Perhaps the largest and most sudden accession to the multitude of mining experts occurred in Colorado upon the discovery of the mines at Leadville. That was an inviting field, and there as nowhere else before the crop of self-made "professors" and "mining engineers" and "experts," seemed to spring out of the ground or to fall from the clouds. Their name was legion, and their performances marvelous beyond credulity. One of the strongest and most effective points of the mining expert is figuring on "ore in eight," and that trick has loosened the purse-strings of many a doubting Thomas among Eastern capitalists. The *Colorado Miner*, published at Georgetown, says that a "genius of this class lately reported on a mine in Clear Creek county, and after several pages of transcendental hooch which had been pumped into him for information about the property, he made the statement that over \$1,000,000 worth of ore was in eight. If he can take out \$10,000 in six months with a profit of \$5,000, the miners of this county will be agreeably surprised. The property is a good one, needing only a large working capital for extensive development, but such reckless and absurd statements only harm the mining interests."

In this city only a few months ago a ready-made "professor" from Leadville, who had been brought from New York as an expert to examine and report upon a gold mine in this State, which had been offered for sale at a round price, declared to a trained and skillful mining engineer and metallurgist, in his own laboratory, that there were "no minos in California—no mines on the Pacific coast. If you want to see mines you must go to Leadville." He uttered this astounding judgment with an easy confidence, which left the hearer in doubt of his own sanity. This class has been the means of placing many a worthless mining claim upon the Eastern market, to the serious detriment of the great and beneficent mining industry of the country.
